

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

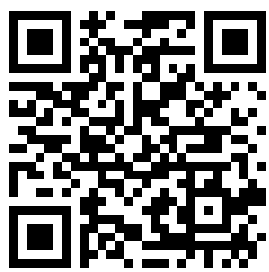
Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.

+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.

+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.

+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.



Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

MEDICAL SOCIETIES.

ÆSCULAPIAN SOCIETY.—Perforating gastric ulcer, laparotomy, recovery; Senile endometritis, 382—Exhibition of cases and specimens, 1027—Cancer of the rectum; Exhibition of cases, 1414

AMERICAN PHYSIOLOGICAL SOCIETY.—The physiological influence of alcohol, 397

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—Annual meeting, 1355, 1577, 1712, 1765

ASSOCIAZIONE MEDICA LOMBARDA.—The latest views on phthisis, 214

BECKENHAM AND PENGE MEDICAL SOCIETY.—The battle of the clubs, 1481

BEDFORD MEDICAL SOCIETY.—Annual meeting, 372—Tetanus treated with antitoxin, 1062

BERLIN MEDICAL SOCIETY.—The bacillus of plague, 777—Over-exertion in cycle-races, 1578

BIRKENHEAD MEDICAL SOCIETY.—Dropsy of knee-joints, 146—Foreign body in bladder, 284—Hypnotism, 506—Gastro-enteritis in children, 925—An outbreak of typhoid fever, 1181—Exhibition of cases and specimens, 1382.

BOLTON AND DISTRICT MEDICAL SOCIETY.—An ethical question, 1249

BOMBAY MEDICAL AND PHYSICAL SOCIETY.—Epithelial xerosis; Necrosis of the internal ear; Foreign bodies in the bladder; Osteomollities; Radiograph of a snake, 1276—Dengue fever; The pneumonia type of plague, 1547

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—Exhibition of specimens and cases; Asthma and hay fever of nasal origin; Undescended testicle, 245—Prevalence of cancer, 524—Tubercle, 885—Exhibition of specimens; Injury to the brachial and cervical plexuses of nerves; A case of tetanus treated by antitoxin, recovery; Lupus of the vagina; Twin labour; Vaginal hysterectomy for cancer, 1149—Acute nephritis; Invaccinated erysipelas; Myxœdema; Recurrent appendicitis; Transposition of the viscera, 1416

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—Milk-supply, 1253

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases and specimens, 251, 539, 885, 1182, 1409

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—The climatic treatment of phthisis, 592; conversazione, 1292

BRITISH GYNÆCOLOGICAL SOCIETY.—Exhibition of specimens; Hysterectomy, 39—Antiseptic midwifery, 221—Annual meeting; Election of officers; Presentation of reports, President's address; Exhibition of specimens; Pan-hysterectomy after clamp operation, 244—Exhibition of specimens and appliances; President's address, 523—The treatment of inoperable carcinoma, 884—Exhibition of specimens; The value of exploratory laparotomy, 1469

BRITISH ORTHOPÆDIC SOCIETY.—Exhibition of cases and specimens, 1382

CHARING-CROSS HOSPITAL MEDICAL SOCIETY.—Food adulteration, past and present, 392

CLINICAL SOCIETY.—Gunshot-wound of the eye; Paroxysmal tachycardia; Fracture of the axis vertebra, 176—Clinical evening; Exhibition of cases, 313—Gastro-enterostomy; Sequel to cases of excision of intestinal growths; Voracious hunger and thirst after injury or disease of brain; Fatal cases of enteric fever without intestinal ulceration, 522—Exhibition of cases, 665—Thrombosis of the veins of Galen after scarlet fever; Sclerema neonatorum; Peripheral hyperostosis; Urobilinuria following the administration of trional, 883—Epidemic of infantile paralysis; Gastrostomy for swallowed œsophageal tube; Removal of cerebral tumour; Extravasation of urine, 956—Sarcoma of the prostate; Ovariotomy in a child; Hydatid cysts of the liver, pleura, and abdominal cavity, 1092—Myeloid sarcoma of the jaw; Congenital dislocation of the shoulder; Hydronephrosis; Muscular dystrophy; Subclavian bruit without any other symptoms; Myositis; Dwarfing of humeri; Symmetrical orbital swellings; Keratosis, 1206.—Chronic hydrocephalus; Wound of the mesentery; Strangulated hernia; Femoral hernia, 1413—Intra-cardiac thrombus; Dissecting aneurysm rupturing into both pleural cavities; Annual meeting, 1546

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—Annual meeting and dinner, 1592

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases and specimens; Agraphia and the question of the existence of a special graphic centre in the cerebrum, 245—Dual brain action and its relation to certain epileptic states, 454—Exhibition of cases and specimens, 628—Discussion on the new city hospital, 919—Renal tumour; Congenital hypertrophy and stenosis of the pylorus; Removal of a fragment of steel from the vitreous humour; Intestinal obstruction; Catgut and silk rolled in balls, 1416; Exhibition of cases and specimens, 1617

EDINBURGH OBSTETRICAL SOCIETY.—Exhibition of specimens; Hæmorrhage from rupture through a mucous cyst; Retention of the menstrual fluid; Extra-uterine gestation, 246—Pressure in the growing pregnant uterus, 595—Extra-uterine gestation; Fœtal malformations, 887—Vaginal hysterectomy; Interstitial pregnancy, 1470—Report on specimen; Culture, diagnosis, and serum treatment of puerperal fever; Morphology of the vaginal segment of the genital tract, 1745

EDINBURGH ROYAL MEDICAL SOCIETY.—Annual dinner, 844

EPIDEMIOLOGICAL SOCIETY.—The spread of the plague, 4, 39, 85—Age incidence in relation with cycles of disease prevalence, 315—Review of the statement of the dissentient members of the Royal Commission on Vaccination, 391, 397, 539, 809, 913—The prevention of tuberculosis, 958—Diphtheria, 1345—The Jenner memorial medal, 1483—Seasonal fluctuations of epidemic diseases, 1546—Annual dinner, 1715—The Russian National Health Society, 1776

FRENCH ACADEMY OF MEDICINE.—Corsets, 558—The manufacture of matches, 777—Diagnosis between gout and rheumatism by the Roentgen rays, 785—Appendicitis, 1056, 1121—Injuries caused by the Roentgen rays; Electricity and music in the treatment of disease; "Anti-alkaloidal vaccination," 1178—Spinal curvature, 1241, 1440—Locomotor ataxy, 1308—The Roentgen rays, 1506, 1641—Gastritis, 1577—Koch's tuberculin, 1713—Rabies, 1773

FRENCH OPHTHALMOLOGICAL SOCIETY—Annual meeting, 1378

FRENCH SOCIETY OF LEGAL MEDICINE.—Syphilis contracted by a wet-nurse, 558

FRENCH SOCIETY OF DERMATOLOGY.—Mercury in non-syphilitic skin disease, 1577

FRENCH SURGICAL SOCIETY.—Election of corresponding members, 397—Surgery of the lung, 558—Exophthalmic goitre, 777—Appendicitis, 932—Suppurative peritonitis, 1308

FRENCH THERAPEUTICAL SOCIETY.—Antipyrin; Chlorosis, 1056

GLASGOW MEDICO-CHIRURGICAL SOCIETY.—Kirstein's autoscope, 211—Exhibition of cases and specimens, 487, 775—General paralysis of the insane; Paralysis of the external rectus muscle; Treatment of diphtheria by antitoxin, 596—Demonstration of Roentgen rays and cinematograph, 920—Excision of the ankle; Operation for gastric ulcer, 1120—The parasite of malaria; Beriberi; Myxœdema, 1241—Exhibition of cases and specimens, 1376, 1504—Election of office bearers, 1576

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Tubal abortion; Broad ligament cysts, 813

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.—Mitral stenosis; Exhibition of cases, 1377

GLASGOW SOUTHERN MEDICAL SOCIETY.—Exhibition of cases and specimens, 776

GRANT COLLEGE MEDICAL SOCIETY.—Bubonic plague in Bombay, 971

HARVEIAN SOCIETY.—Some notes on ovarian tumours, 178—The President's address; Election of officers; Conversazione, 316—Smoking at non-clinical meetings; Polyneuritis in children; The oxygen treatment of ulcers, 448—Chronic interstitial nephritis in childhood, 585, 728—The dangers and diagnosis of breech presentation and its treatment by external version towards the end of pregnancy, 592—Exhibition of cases, 738—Some common troubles following upon childbirth, 884—Difficult catheterism, 1062—The anæsthetisation of children, 1275, 1334—Some resources in the diagnosis of nervous diseases, 1414—Exhibition of cases, 1547

HUNTERIAN SOCIETY.—Exhibition of specimens, 243—Sprains and their treatment; Pelvic cellulitis, 381—William Hunter, anatomist, physician, and obstetrician, 504—Annual meeting, 636—Torticollis and its treatment, 666—Exhibition of specimens, 811—Cerebellar tumour; Mental disorders of the climacteric period, 959—Exhibition of cases, 1148—Cerebellar disease; Headaches, 1275

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—Exhibition of cases, 379, 674—Annual meeting and dinner, 997—Excursion, 1533

JOHNS HOPKINS HOSPITAL MEDICAL SOCIETY.—Treatment of ectopic pregnancy by vaginal puncture, 972

KIDDERMINSTER MEDICAL SOCIETY.—Exhibition of cases and specimens, 454; Punctured wound of abdomen; Exhibition of cases and specimens, 1682

LARYNGOLOGICAL SOCIETY OF LONDON.—Annual meeting, 285

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Spontaneous rupture of the female bladder; Some instruments of local and historical interest, 453—Rapid absorption of tuberculous masses in the abdomen; Blockage of common duct by a gall-stone, 594—Exhibition of specimens, 667—Gastric ulcer; Fruit of cream of tartar tree, 885—Exhibition of cases and specimens, 1275—Recovery after a very large dose of nitrate of silver; Complications following operation for varicocele, 1346—Bacteriological diagnosis of enteric fever; Mesenteric cysts; Triplet placentæ; Transposition of the heart, 1470

LIVERPOOL MEDICAL INSTITUTION.—Nomination of office bearers, 73—President's address, 181—Election of office-bearers, 285—Report of the council for 1896, 348—Exhibition of cases; Castration for enlarged prostate, 382—Exhibition of specimens; Serum diagnosis of typhoid fever, 451—Operation *versus* Glasses for squint; Litholapaxy in children; Tubo-ovarian abscess; Fibrinous rhinitis; Permanent cure of nasal duct obstruction, 593—Exhibition of specimens, 742—Treatment of dacryocystitis, 667, 812—Stone in the bladder, 812—Calculus in the ureter; Plastic operation for lupus; Malaria in Central Africa; Excision of the rectum, 960—Intermittent hemiplegia; Tetanus; Enucleation of uterine fibroids; Operative treatment of injured and painful blind eyes, 1095—Malignant growth of the orbit; Tumour of the pons cerebri; Presystolic murmur without mitral stenosis; Addison's disease; Peroneal spasm, 1208

MANCHESTER MEDICAL SOCIETY.—Annual meeting, 279—Fractures of the lower end of the humerus, 493—Subphrenic abscess; Detection of sugar in the urine, 741—Peripheral neuritis in pregnancy and the puerperum; Notification of phthisis; Unusual condition of the spleen, 1148

MANCHESTER PATHOLOGICAL SOCIETY.—Exhibition of specimens, 383—The bacteriological diagnosis of typhoid fever; Exhibition of specimens, 524—Primary tuberculous tenosynovitis; Pathology of missed abortion; Sarcoma of the forearm, 812—Exfoliating cystitis; Recurrent appendicitis; Pernicious anæmia; Exhibition of specimens, 1209—Solid tumours of the ovary; Cystic sarcoma of muscle; Intra-hepatic thrombosis; Intra-ocular hydatid cyst; Exhibition of specimens, 1415

MANCHESTER THERAPEUTICAL SOCIETY.—First general meeting, 1771

MEDICAL SOCIETY OF LONDON.—Wandering spleens; Prognosis of pneumothorax, 174—Operation for vesico-vaginal fistula; resection of sigmoid flexure; Laparotomy for strangulation by a band twice in the same patient, 315—Diseases of the nose and throat in relation to general medicine, 361, 539, 672, 727—Exhibition of cases and specimens, 446—Traumatic neurasthenia; Value of the cystoscope in the early diagnosis of renal conditions, 591—Excision of knee, 732, 738—Intestinal neurosis, 738—Dinner, 752—Election of honorary Fellows, 827—Intestinal anastomosis; Senile decay, 882—Extroversion of the bladder; Spastic hemiplegia; Acromegaly; "Baker's cyst" of the knee; Osteotomy for deformity; Sarcoma of the thumb; Spontaneous fractures; Multiple tumours of the skin, 1091—Senile tuberculosis, 1206; Treatment of gout by an exclusive meat diet and hot water, 1206, 1343—Conversazione, 1289, 1428—Election of officers; Excision of rectum, 1343—The Medical Society of London in the eighteenth century, 1389, 1428

MEDICO-PSYCHOLOGICAL ASSOCIATION—Meeting of the South-Western Division, 372, 1028—The housing of the insane and the size of asylums, 740—Examinations for the certificate in nursing, 766, 1358—Next annual meeting, 773—General meeting, 1341

MIDLAND MEDICAL SOCIETY.—A plea for more accurate and systematic feeding of infants, 452—Exhibition of cases and specimens, 595—Mediastinal tumour; Resection of colon; Spinal caries, 886—Election of officers; Paræsthesia; Exhibition of cases and specimens, 960

Hosted by Google

NEUROLOGICAL SOCIETY.—Presidential address on heredity in neurosis, 178
NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—Exhibition of cases and specimens; Recurrent appendicitis, 382
NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Election of officers for 1897; Exhibition of specimens; The development of the placenta, 317—Exhibition of specimens, 666—Porro's operation; Kolpo-panhysterectomy for cancer; Twisting of the pedicle in ovarian tumours; Exhibition of specimens, 961—Atresia vaginæ and uterus didelphys, 1382—Treatment of puerperal septicæmia; Exhibition of specimens, 1683
NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—Exhibition of cases and specimens, 40—The death of Mr. Broadbent; Congratulations to Lord Lister; Exhibition of cases and specimens, 318—Exhibition of cases, 887
NOTTINGHAM MEDICO-CHIRUGICAL SOCIETY.—Some points in abdominal surgery; Exhibition of specimens, 107—The method of serum diagnosis in typhoid fever, 180—Treatment of nævi by electrolysis; Exhibition of cases and specimens, 317—The insanity of childhood; Exhibition of cases and specimens, 464—Removal of the uterine appendages, 593—Different varieties of aortic regurgitation, 741—Composition and properties of water, 1062—Dentistry and general practice, 1311—Pelvic hæmatocele considered from the modern standpoint, 1662—Submaxillary cellulitis; Contagious Diseases Act from a sanitary aspect; Exhibition of cases and specimens, 1715
OBSTETRICAL SOCIETY.—The etiology of eclampsia; Breech presentation with extended legs; Exhibition of specimens, 177—Exhibition of specimens; Annual general meeting; Election of officers, 446—Puerperal fever in England and Wales, 643—Cyclical or wave theory of menstruation, 739—The treatment of placenta prævia by Champetier de Ribes' bag; Exhibition of specimens, 1094—Chronic axial rotation of an ovarian cyst; Abdominal pregnancy at full term, operation at the twelfth month, recovery, 1344—Parturition during paraplegia, 1616
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—Transplantation; Retarded eruption; Methods of preventing deformity after removal of portions of the mandible, 179—Deafness following bilateral dislocation of the jaw occurring during extraction; Cement and amalgam as a filling, 447—Copper amalgam as a filling material; The discolouration of copper amalgam, 739—Microscopical aspects of certain lesions induced by dental caries, 1094—Annual general meeting; the bite of the upper and lower teeth, 1716
OPHTHALMOLOGICAL SOCIETY.—Spontaneous recovery of a retinal detachment; Retention cyst of the lacrymal gland or "dacryops," 380—Discussion on retro-ocular neuritis, 683, 808, 958—Exhibition of cases and specimens, 1344—Filaria loa; Sympathetic ophthalmitis; Blindness following blows on the head; Exhibition of cases, 1744
PATHOLOGICAL SOCIETY.—The biology and morphology of the tetanus bacillus; Exhibition of specimens, 106—Non-calcifying plastic osteitis; Report on a museum specimen of malignant enchondroma of the testicle; Exhibition of specimens, 242—Hæmorrhagic diphtheria; Ulcerative endocarditis affecting a malformed aortic valve; Graves's disease with persistence of the thymus gland, 380—Ringworm fungi; Exhibition of specimens, 521—Exhibition of cases and specimens; Epithelioma of the penis, 664—"Sable intestinal"; Gummatous enlargement of the kidney; Minute anatomy of intussusception; Giant-celled tumours of the skin; Occlusion of the duodenum, 807—Actinomycosis of the pleura and chest walls; Cyst of omentum; Concretions of the rectum; Traumatic hydrocephalus; Infective venereal tumours in dogs; Tuberculous peritonitis associated with an inguinal pouch of the peritoneum; Healthy œsophagus ruptured by vomiting, 1025—Lymphadenomatosis of the bones; Dermatitis maligna; Bodies in the vermiform appendix; Rupture of the heart; Mucosal cysts; Gumma of the spleen, 1273—Teratoma of the scalp; Trophic affections of the joints; Impacted gall-stone; Acromegaly, 1412
PHILADELPHIA PATHOLOGICAL SOCIETY.—Cardiac hydrothorax, 847
PLYMOUTH MEDICAL SOCIETY.—The present position of serum therapeutics, 333—Exhibition of cases and specimens, 562—The case of Mr. R. B. Anderson, 1346
POOR-LAW MEDICAL OFFICERS ASSOCIATION.—Poor-law Officers Superannuation Act, 1415
ROCHDALE AND DISTRICT MEDICAL SOCIETY.—Protest against the Midwives Registration Bill, 562
ROYAL ACADEMY OF MEDICINE IN IRELAND.—Acute intestinal obstruction, 108—Widal's method of diagnosing enteric fever; Concurrent scarlet fever and enteric fever, 181—Pathological conditions of the heart; Achorion Schönleinii; Pyogenic organisms; Trichinosis, 319—Excision of the tongue, 455—A case of diabetes insipidus, 525—The applied anatomy of the rectum, 668—The typhoid bacillus, 742—Bubonic plague, 813—Nephro-lithotomy and nephrectomy; The anticipation of post-partum hæmorrhage, 888—Dilatation of the stomach; Relapse in scarlet fever; Celandine in cancer, 961—Infective endocarditis; Roentgen photographs; Locomotor ataxy, 1096—Strangulated femoral hernia; Intestinal anastomosis, 1209—The diarrhœas of children, 1276—Exhibition of specimens; Strangulation of an intra-ligamentous fibro-myoma; Ergot in obstetrics, 1471—The dissemination of micro-organisms from sewer air; The report of the Vaccination Commission, 1416—Distension of the bladder with air in suprapubic cystotomy; Pyloroplasty; Fracture of the metacarpal bone of the thumb, 1617—The recent failure of hospital accommodation in Dublin, 1683—A case of Charcot's disease, 1746
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Infantile cerebral degeneration, with symmetrical changes at the macula, 174—Perforating typhoid ulcer treated by operation and suture, recovery; Jaundice and perforation of the gall-bladder in typhoid fever, 312—The urine in typhoid fever; Nervous symptoms in typhoid fever, 445—Surgical physiology of the foot, 591—Annual meeting, 664—Clinical bearing of some experiments on peritoneal infections; Removal of a large solid tumour from the retro-peritoneal space, 737—Parasite of malarial fevers at Sierra Leone; Pulsating empyema, 881—Hernia cerebri; Non-tuberculous posterior meningitis, 1090—Non-tuberculous posterior basic meningitis, 1205—The relations between bodily development, nutrition, and brain conditions in their pathological aspects, 1342—Ligature of the subclavian artery for aneurysm; Ligature of the carotid arteries for tonsillar hæmorrhage; Irreducible hernia, 1468—Musical mitral murmurs in connexion with aortic stenosis, 1615
SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Exhibition of specimens, 107—Exhibition of cases, specimens, and skiagraph; Foreign body in the œsophagus, 316—Exhibition of cases and specimens, 452—Porro's operation, 594—A case of tetanus, 742—Exhibition of cases and specimens, 886—Exhibition of cases; Surgical treatment of gall-stones, 1065
SOCIETA MEDICO-CHIRURGICA OF BOLOGNA.—Diagnosis of tumour of the cerebellum, 291
SOCIETY OF ANÆSTHETISTS.—The occurrence of pneumonic conditions after the administration of anæsthetics, 804, 1026—A new anæsthetic inhaler, 1026
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The Royal Commission on Vaccination, 197, 450, 635, 666—The epidemic of small-pox at Gloucester, 1027—Election of president, 1107—Sewer ventilation and health, 1207
SOCIETY FOR THE STUDY OF INEBRIETY.—The proposed legislation for habitual drunkards, 754—Treatment of disease without alcohol, 1099
SOUTH-WEST LONDON MEDICAL SOCIETY.—Studies in diagnosis, 151, 341—Clinical meeting, 706—Acute inflammation of bone in children and young persons, 811—The bacillus of diphtheria, 1209—The welfare of the general practitioner, 1516
SWANSEA MEDICAL SOCIETY.—The progress of surgery and the treatment of simple fractures, 1599
ULSTER MEDICAL SOCIETY.—Demonstrations and exhibition of specimens, 776
VIENNA MEDICAL SOCIETY.—Medical aid societies, 558—Pemphigus vegetans, 559—The pituitary body and the thyroid gland, 703
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A plea for a more precise classification of disease; Six cases of strangulated hernia in infancy and early childhood, 180—The menopause viewed from a gynæcological standpoint, 449—Exhibition of cases, 740—Emphysema, 1062—The value and safety of abdominal exploration in obscure cases, 1346—Annual dinner, 1561—Exhibition of cases, 1617
WIGAN MEDICAL SOCIETY.—Astragalectomy, 328—Annual meeting, 561—Coin in the œsophagus, 1742
WORCESTER MEDICAL SOCIETY.—Annual meeting, 285

REVIEWS AND NOTICES OF BOOKS.

Diseases of the Eye and Ophthalmoscopy: by Dr. A. Eugen Fick; authorised translation by Albert B. Hale, A.B., M.D., 41—Surgical Diseases of the Ovaries and Fallopian Tubes, including Tubal Pregnancy: by J. Bland Sutton, F.R.C.S. Eng., 42—Physiologie des Menschen und der Säugethiere: von Professor Dr. Immanuel Munk; vierte auflage, 42—Traité d'Electrothérapie Oculaire: par le Dr. P. Pansier; avec une Préface de M. le Dr. Valude, 108—Life in West London: a Study and a Contrast: by Arthur Sherwell, 109, 1472—Eléments d'Ophthalmologie Journalière: par les Drs. A. Puech et C. Fromaget, 110—At the Court of the Amir: by John Alfred Gray, M.B. Lond., 110—Sell's Dictionary of the World's Press, 110—Janus: Archives Internationales pour l'Histoire de la Médecine et pour la Géographie Médicale, 110—The Modern Treatment of Stone in the Bladder by Litholapaxy: by Surg.-Lieut.-Col. P. J. Freyer, M.A., M.D., M.Ch. R.U.I.; second edition, 182—A Practical Guide to Meat Inspection: by Thomas Walley, M.R.C.V.S.; third edition, 183—Roentgen Rays and Phenomena of the Anode and Cathode: by Edward P. Thompson, M.E., E.E., 183—Practical Radiography: by H. Snowdon Ward, 183—Diagrametres (Hygiene): by W. H. Knight, 183—Cheese and Cheesemaking: by James Long and John Benson, 184—The Medical Environment: by D. Campbell Black, M.D. Glasg., F.R.S. Edin., 184—Rough Notes on Remedies: by William Murray, M.D. Durh., F.R.C.P. Lond., 184—An American Text-book of Applied Therapeutics, for the Use of Practitioners and Students: edited by J. C. Wilson, M.D., assisted by A. Eshner, M.D., 247—Nouveaux Éléments d'Ophthalmologie: par H. Truc et E. Valude, 249—An American Text-book of the Diseases of Children: edited by Louis Starr, M.D., assisted by Thompson S. Westcott, M.D., 250—A System of Surgery: edited by Frederic S. Dennis, M.D., assisted by John S. Billings, M.D., LL.D., D.C.L., vol. iii., 320—Kurzgefasstes Lehrbuch der Mikroscopisch-Gynäkologischen Diagnostik: von Dr. Josef Albert Amann, Jr., 321—The Causes and Treatment of Rheumatoid Arthritis: by Samuel Hyde, M.D. St. And., 321—Dod's Parliamentary Companion, 321—Army Medical Department Report for the year 1895, 338, 475, 616. — Injuries and Diseases of the Genital and Urinary Organs: by Henry Morris, M.A., M.B. Lond., F.R.C.S. Eng., 384—Gout and Goutiness and their Treatment: by William Ewart, M.D. Cantab., F.R.C.P. Lond., &c., 385—De la Nature de l'Epilepsie: by Fr. Hallager, 386 — Recherches Cliniques et Thérapeutiques sur l'Épilepsie, l'Hystérie, et l'Idiotie: par Dr. Bourneville, 386—Handbuch der Gynäkologie: Herausgegeben von J. Veit (Leyden), 456—Essays and Addresses: by Sir John Russell Reynolds, Bart., F.R.S., M.D. Lond., LL.D., &c., 457, 612—Hygiene for Beginners: by Ernest Septimus Reynolds, M.D., F.R.C.P. Lond., 458—A Manual of Infectious Diseases: by E. W. Goodall, M.D. Lond., 459 — Transactions of the American Gynæcological Society, 459—L'Hygiène Publique de Hongrie, 525—Ectopic Pregnancy, its Etiology, Classification, Embryology, Diagnosis, and Treatment: by J. Clarence Webster, B.A., M.D., F.R.C.P. Edin., 526 — Deformities: a Treatise on Orthopædic Surgery, intended for Practitioners and Advanced Students: by A. H. Tubby, M.S. Lond., F.R.C.S., 597—Aristotle on Youth and Old Age, Life and Death, and Respiration: translated by W. Ogle, M.A., M.D.

LIST OF ILLUSTRATIONS.

COLOURED.

Drawings of Micro-organisms as seen with the Microscope and of Characteristic Cultures in Tubes, accompanying paper on Actinomycosis and Madura Disease (Professor E. M. Crookshank), 12
Graphic Diagrams to illustrate article on Some Small-pox Statistics (Dr. S. Coupland), 510

Drawings of Ovaries and Fallopian Tubes, accompanying paper on Pelvic Inflammation in Women (Dr. W. Duncan), 8, 9
Drawings of Cattle, Jawbones of Cattle, Human Liver and Foot, &c, accompanying paper on Actinomycosis and Madura Disease (Professor E. M. Crookshank), 12, 13, 14, 15, 17
Culture Tubes, described in paper on Streptococcus Infection (Mr. G. L. Cheatle), 27
Portraits of Patients referred to in paper on Acromegaly (Dr. I. Banks), 28, 29
Drawings of a case of Dislocation of the Head of the Femur into the Obturator Foramen before and after Treatment (Mr. G. R. Turner), 33, 34
Perigraph and Diagrammatic Map of the External Surface of the Brain, described in paper on a New Method of Localising Brain Lesions (Mr. R. H. Cox), 35
Acoustic Bladder Sound, 44
Apparatus described in article on the Lawrence Process of Softening and Sterilising Water, 64
Diagrams accompanying paper on Reduplication of the Second Sound of the Heart (Dr. A. G. Phear), 97
Improved Œsophageal Probang (Dr. E. M. Sympson), 112
Portrait of Lord Lister, the first Medical Peer, 127, 1695
Photo-print of the Tomb of Louis Pasteur at the Institut Pasteur, 129
Drawings illustrating a case of Excision of the Upper Half of the Rectum for Cancer (Mr. J. J. Clarke), 163
Two Radiographs of the Pelvis of a Boy; one shows a Calculus in the Bladder, the other was taken after the performance of Lithotapaxy (Dr. A. P. Laurie and Dr. J. T. Leon), 169
Section of Sarcoma of the Liver, described in accompanying paper (Dr. Byrom Bramwell), 172
"Penetrator" Roentgen Ray Focus Tube, 187
Double-peaked Cycle Saddle, 183
Plan of the New Operating Theatre at St. George's Hospital, 267
"Argus" Retroscope (Surg.-Capt. Cockerill), 289
Illustrations accompanying paper on Various Forms of Talipes as depicted by X Rays (Mr. R. Barwell), 307, 308, 309
Skiagram showing Coin impacted in Œsophagus, also drawing of Coin-catcher described in accompanying paper (Mr. H. Marsh and Mr. A. A. Bowlby), 313, 314
New Obstetric Binder (Mr. A. D. Owen), 323
Invalid's Table, 323
Portrait of the late Dr. E. Ballard, 342
Drawings illustrating a case of Resection of the Radius for Sarcoma (Mr. E. H. Douty), 376
Dilating Urethral Bougie (Dr. Natale Amici), 387
"Mammoth-tusk" Gag for Senile and Edentulous Jaws (Dr. H. Snow), 387
Portrait of the late Sir T. S. Wells, 398
Illustrations accompanying lecture on the Pathology and Surgery of Intussusception (Mr. D'Arcy Power), 428
Photo-prints and skiagraph of cases of Deformity of the Hand relieved by operation (Mr. N. Smith), 431, 432
Gravid Fallopian Tube (Mr. J. B. Sutton), 432
Diagram accompanying paper on Traumatic Epilepsy (Mr. G. P. Newbolt), 445
A New Trephine (Mr. W. Falla), 460
Modified Nasal Style and Probe (Mr. T. H. Bickerton), 461
Weber-Parkes Medal, 475
Silent Coal Box, 499
Photo-print of the Heart from a case of Ulcerative Endocarditis (Dr. A. E. W. Fox), 521
Automatic Spring Tonsil Guillotine (Mr. R. B. Popham), 527
Improved Tonsillotome (Dr. F. Spicer), 527
New Tonsil Forceps (Dr. G. K. Finlay), 528
Maps, Plans, &c., illustrating THE LANCET Special Commission on the Metropolitan Water-supply:—Outline Maps of London and the surrounding Counties, 542, 543; West Middlesex Company (Reservoirs, Filter Beds, principal Mains, and District supplied), 613, 615; Chelsea Company (principal Mains, District supplied, Intakes, and Filter Beds), 685, 686; Lambeth Company (principal Mains, District supplied, two Stations, and two Reservoirs), 758, 760; Southwark and Vauxhall Company (principal Mains, Filter Beds, &c.), 828, 829, 830, 831, 901, 903; Kent Company (District supplied, Section of Geological Strata), 977, 1109; Map of London in the year 1000, 1162; East London Company (Hanworth Station, District supplied, Course of the River Lea, Reservoirs at Walthamstow, Lea Bridge Station, &c.), 1290, 1291, 1359, 1429, 1485; Grand Junction Company (Stations at Hampton, Kew-bridge, Hanger-hill, and Campden-hill, Filter Screen, principal Mains, and District supplied), 1703, 1760, 1761, 1762
Diagrams to illustrate article on Some Small-pox Statistics (Dr. S. Coupland), 585
Diagram Maps of London to illustrate paper on Puerperal Fever in England and Wales (Dr. C. J. Cullingworth), 646, 647
Apparatus described in paper on the Application of the Serum Test to the Differential Diagnosis of Typhoid and Malta Fever (Dr. A. E. Wright and Surg-Capt. F. Smith), 657
Diagram of Thorax and copy of Roentgen Photograph showing Bullet in the Body, accompanying article on Bullet lodged behind the Clavicle (Mr. H. Morris), 662, 663
Diagrams showing Sections of Femur and Tibia, illustrating paper on Excision of the Knee (Mr. C. B. Lockwood), 734
New Combination Speculum (Mr. A. Duke), 746
Perimeter Charts and Reproductions of Patients' Handwriting and Drawings, accompanying papers on Illustrative Cases of Aphasia (Dr. Byrom Bramwell), 797, 798, 870, 951, 952, 1019, 1020, 1021, 1022, 1076, 1077, 1080, 1142, 1143, 1259, 1405, 1406, 1407
Skiagraph of Knee-joint and Fractured Femur (Surg.-Col. W. F. Stevenson and Surg.-Maj. Whitehead), 804
Improved Ether Inhaler (Mr. H. B. Gardner), 816
Portrait of Patient, accompanying paper on Congenital Malformation of the Nose (Mr. W. R. H. Stewart), 877
Metal Hospital Inhaler (Dr. J. F. W. Silk), 892
Improved Hypodermic Case, 892
Improved Mouth-opener and Gag (Dr. F. W. Cock), 892
Chart of the Island of Bombay, together with Graphic Curves showing Mortality and various Atmospheric Conditions, illustrating paper on the Plague in Bombay, 915, 916
Diagrams of Brain, accompanying Lumleian Lectures on Aphasia and Other Speech Defects (Dr. H. C. Bastian), 935, 937, 1012, 1015, 1190, 1191
Roentgen Photograph, giving a Distorted Image of a Normal Leg, as described in paper on Experimental Distortion (Dr. W. S. Hedley), 954
Celluloid Spray Producer, 966
Tracheotomy Pilot (M. D. Harmer), 966
Improved Uterine Flushing Curette (Dr. C. F. Marshall), 1030
Artificial Larynx (Professor T. P. A. Stuart), 1083, 1084
Clinical Chart accompanying paper on Cases of Tetanus (Mr. Marsack), 1089
Sarcoma of the Prostate (Mr. J. Griffiths), 1093
Celluloid Cylinder Dressing-box, 1098
Knife for Slitting open the Tonsils (Dr. A. Bronner), 1099
Spring Pressure Gauge Calipers (Mr. J. MacMunn), 1099
Diagram accompanying paper on Intussusception treated by Laparotomy (Mr. R. L. Knaggs), 1138
New Surgical Needles, 1152
Combination Couch-chair for the Consulting-room (Mr. M. G. McElligott), 1215
New Pattern of Scissors for Perineal Repair (Mr. L. Tait), 1216
New Patella Splint (Mr. F. Dalton), 1216

A Clinical Lecture

ON

INSULAR SCLEROSIS AND HYSTERIA;

Delivered at the National Hospital for the Paralysed and Epileptic, Queen-square, on Nov. 10th, 1896,

BY THOMAS BUZZARD, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—It need scarcely be said that to enter at all fully into the subject either of Insular (disseminated) Sclerosis or of Hysteria would require a good many lectures. My object to-day is to give you a sketch illustrative of a single point, viz.—the extraordinary liability of Insular Sclerosis to be diagnosed as Hysteria. In making a sketch of a landscape from nature the art largely consists in knowing what to leave out. In my sketch it will be understood, in like manner, that everything which is not essential to the particular object in view will necessarily be omitted.

Of the two patients present, one, aged forty-two years, I have the opportunity of showing by the courtesy of Dr. Hughlings Jackson; the other, aged twenty-eight years, is under my own care. The first is a married woman who, ten years ago, began to suffer from giddiness and complained of weakness in her legs, which has continued to the present time, and has been accompanied occasionally by pains. Four years ago she first noticed trembling and inability to hold things with her right hand, and two years ago the left arm became similarly affected. One year ago she began to have delay in micturition, and more recently incontinence of urine. She suffered also from double vision. During the last six months there has been some trembling of the hand and her articulation has been impaired. On admission to the hospital she appeared to be well nourished, and nothing wrong was found in the digestive, circulatory, or respiratory systems. Her mental state appeared to be normal. Her utterance was slow and inclined to be syllabic. There was diminution of power in the arms and great incoördination in voluntary movements. There was no marked wasting. She could not walk, and when lying was unable to raise the legs from the bed. The legs were stiff and spastic. The sensory system was unimpaired. Of the organic reflexes the act of swallowing was normal; there was complete loss of control over the bladder; the bowels were constipated. Of the superficial reflexes the abdominal and epigastric were absent, but the plantars were present. (I shall have something to say presently about the retention of the plantar reflex.) Of the deep reflexes those at the knees were exaggerated. There was no ankle clonus. There was very marked nystagmus. The vision of the right eye was $\frac{6}{9}$, Jaeger 12 (− 1); that of the left eye was $\frac{6}{9}$, Jaeger 7 (− 3). The optic discs were pale. The patient's present condition will be seen to correspond with this description, for which I am indebted to Dr. Harris, senior house physician. She may be taken as a typical example of insular sclerosis. She has slowly but uninterruptedly grown worse since her illness commenced, some ten years ago, and there is no record of a diagnosis of hysteria having been made in the earlier stages of her disease. If this be so it is a rare exception. Both in hospital and private practice we almost invariably find that a female patient presenting a characteristic picture of insular sclerosis has in the earlier part of her illness been considered, for longer or shorter periods, to be suffering only from hysteria.

Before proceeding to dwell in some detail on this point I will show you the other patient, a single woman aged twenty-eight years, who applied at this hospital in March, 1894, on account of a difficulty in walking from which she had suffered more or less for ten months. It appeared that in May, 1893, she began to complain of weakness of the left arm and leg. She dragged the leg a little, and it felt numbed, "like a log of wood." She had had some considerable mental trouble before this, and the symptoms were set down to "hysteria." This diagnosis appeared to be confirmed when, in the course of a month, the arm had recovered. Although her leg dragged a little she continued to walk until February, 1894. There had been a progressively increasing weakness, which at Christmas, 1893, had extended slightly to the right leg. On examination in the out-patient department the knee jerks were found to be very well marked on both sides. Ankle clonus was obtained readily on the left side at the first attempt, but on the second trial it could not be elicited. There was no sign of ankle clonus on the right side. There was no nystagmus and there had not been any double vision. On the other hand, micturition had been inclined to be precipitate. The patient was a well-grown, healthy-looking young woman. Some doubt was felt by my colleague in the out-patient department as to the diagnosis of this case, and she was sent to Finchley, to our convalescent home, to be under observation and treatment. In May it was noted that she walked much better. It was also remarked that she would get better one day and then worse again. On May 3rd ankle clonus was observed to be definite, though not prolonged, on each side, and about equally well-marked in the two legs. At this time the plantar reflex was present on the right side, but doubtfully expressed on the left. Sensation was apparently normal to touch and pain. On May 31st it was noted that she walked much better—in fact, fairly well; but the left leg was considered rather weaker than the right. There was now an attempt at ankle clonus in the right leg and on the left side it was well marked. For the first time, too, some fine though definite nystagmus was noted in the left eye. In the right eye this was barely perceptible. At this date it was remarked that no plantar reflex was obtained, but the patient appeared to feel both touch and the prick of a pin well. She was discharged from Finchley, but continued to attend the out-patient department in Queen-square till October, 1894, when she was admitted into the hospital for five months, improving considerably during this time under treatment. She was discharged in February, 1895, and readmitted last August in the condition which she now presents. The patient keeps her bed, but can walk alone for a very few minutes and then becomes exhausted. Her gait is very staggering and the act of walking occasions incontinence of urine. The left foot is slightly dragged. When recumbent she can just lift the left leg off the bed, the right being much stronger. The left arm is weaker than the right, but its movements are fairly good. Sensation appears to be normal and equal on both legs and arms. The patient can stand with feet together, the eyes being closed. She can thread a needle if given plenty of time, but is very clumsy and shows tremor in picking up a pin, especially with the left hand. This is also noted when she touches the forehead with her finger. There is incontinence both in regard to the bladder and rectum. The knee-jerks are greatly in excess and there is double ankle clonus. The plantar reflexes are present. There is marked horizontal nystagmus in each eye. Two years ago it appears that the sight of the right eye was dim for a time, but now she says that she can see perfectly, and in effect V = $\frac{6}{9}$ and Jaeger 1 with each eye. Notwithstanding this, when we examine the fundus oculi with the ophthalmoscope we find the optic discs pale, the right showing rather more pallor than the left. I shall presently have to advert to an important feature in the state of her visual fields.

I suppose it can hardly be doubted that both these patients are examples of organic disease and probably of insular sclerosis. Yet the last case was considered before her admission to be one of hysteria, and in hospital some doubt was at first felt as to the nature of her affection. This is evidenced by a note on the out-patient letter. The patient was first examined in March, 1894, and under the heading "Diagnosis" a note of interrogation appears. On May 31st, when the patient had been under observation for two or three months, the following note was made: "Diagnosis uncertain. Thought to be perhaps hysterical, but the definite ankle clonus and the observation of slight nystagmus rather suggest disseminated sclerosis."

I take it that we have all of us at various times given the name of hysteria to an early stage of insular sclerosis. One reason for the common fallacy in diagnosis appears to be that we have somehow failed to remember that insular sclerosis does not spring suddenly into existence in a typical form. Like most other chronic or sub-acute ailments it has to go through a budding period, during which the aspect presented differs much from that of the full-blown disease. Several years ago I expressed the opinion that "many symptoms which have come to be considered characteristic of hysteria will, if examined by the light of improved knowledge and experience, be relegated to disseminated sclerosis." In the case just shown you there are illustrations of this. The sudden loss of power in a limb, occurring after mental shock in an otherwise apparently healthy girl and passing off completely in a

Hosted by Google

month, is a symptom which is practically certain to be set down to hysteria. And so with the dimness of vision in one eye of temporary character, recovering without treatment; and, again, the dragging of a leg, which felt "numbed and like a log of wood." Whatever may be the case with regard to hysteria I have no hesitation in saying that these are as much symptoms of insular sclerosis as cough is of bronchitis or pain of peritonitis (of course, this is not to say that the symptoms are pathognomonic). I would therefore urge you, when you come across such symptoms in an apparently healthy young woman, to remember that they may possibly point to insular sclerosis. Whatever you think of them do not jump to the conclusion that they are any proof that the girl is only suffering from hysteria. Insular sclerosis must be studied in its infancy, so to speak. The full-grown disease is frequently not recognised, the infant disease practically never. In its infancy, according to my observation, the name given to insular sclerosis is "hysteria." This is not a hasty expression of opinion; it is founded upon observation of the sequels of numerous cases during the last twenty years. Some of these have been patients of my own, the progress of whose cases has taught me that I had been in error in originally regarding them as examples of hysteria. Let me refer in the briefest possible manner to some cases illustrating this point which have more or less recently come under my notice in private practice.

CASE 1.—A single woman at twenty-one years of age suffered from weakness in her legs and also in the left arm. After a few months the left hand recovered and then the right hand became weak, so that she could scarcely write for three months. Since then sometimes one and sometimes the other leg has dragged. Her case had been treated always as one of hysteria. When I saw her, four years after the commencement, examination showed nystagmoid movements of the eyes, inability to lift the knees or, except to a trifling degree, to extend the legs, incontinence of urine, grasp of the right hand very weak, that of the left a little stronger, spasticity of legs.

CASE 2.—A married woman aged forty years. For three and a half years she had been unable to walk properly, though at times this had very greatly improved. Six years ago she had diplopia for two months after a great shock. For the last six months she had been getting worse. When seen by me the gait was staggering and the knee-jerks were exaggerated. There was double ankle clonus. There was no manifest unsteadiness of the arms. The sight of the left eye was much better than that of the right. The right optic disc was distinctly pale, the left probably normal. Some weakness of the bladder. She had been treated as a case of hysteria.

CASE 3.—A single woman aged thirty-five years. Difficulty in walking had been observed for four years, and especially for two years, past. For a long time she could not retain urine, but that is now better. Her gait was staggering and stiff. Her knee-jerks were exaggerated and there was double ankle clonus. There was no tremor of the hands on voluntary movement. The first appearance of symptoms was after mental shock and physical fatigue. There was no nystagmus or articulatory difficulty. At times she has improved, but has never been able to run. Medical advisers, of whom she has seen three, all agreed that it was a nervous functional affection, that "it was merely a matter of time and she would recover." She has been told that she could "throw it off by her will." The right disc is paler than the left and sight of the left eye rather better than that of the right.

CASE 4.—A married woman aged thirty-nine years. For many years she had had attacks in which she "would feel that she could not walk." Five years ago she was very anæmic and lost power in her legs, but quite recovered under chalybeate treatment and walked up hills. Seven years ago she lost the use of one arm and saw double; she was in bed for three months, during which the diplopia continued. When seen by me there was nystagmus and marked tremor of the right hand on voluntary movement, so that she was obliged to carry a cup to the lips with both hands. She had been treated as a case of hysteria and had twice undergone Weir-Mitchell treatment. The physician by whom she was sent to me, however, doubted the correctness of this diagnosis, and I agreed with him that it was a case of organic disease. I thought it one of insular sclerosis. Some months later I found partial paralysis of the right external rectus muscle. The sight of the right eye was $\frac{6}{18}$, and that of the left $\frac{6}{9}$. There was some pallor of both optic discs, especially of the left.

CASE 5.—A married woman, whose present age is thirty-seven years, was seen by me in 1883, and she underwent Weir-Mitchell treatment with my consent on account of loss of power in her legs with transitory loss of feeling in the left arm, which had appeared to be of hysterical character. I lost sight of her and did not see her again for thirteen years. Her condition was then as follows. She could not stand, the lower limbs being in a state of rigid contracture. Her speech was hesitating and slurring and her manner vacant. She was unable to retain the urine night or day, this condition having followed a period of inability to empty the bladder except after great delay. On testing the vision it was found that she could only read Jaeger No. 6 with the right eye, whilst with the left she could not see No. 14. Ophthalmoscopic examination showed both discs (especially the left) greatly atrophied, even the nasal side being grey. There were nystagmiform movements in each eye. At the same time she could carry a glass to her lips with either hand very fairly.

CASE 6.—A single woman aged nineteen years, at Christmas, 1892, had an attack of facial paralysis which lasted a month. On recovering from influenza in February, 1893, she found some loss of control over her legs in walking; she staggered and stumbled. In about six months she had recovered the power in her legs except that she could not walk far. Her complaint had been called hysterical paralysis. When seen by me she had weakness of the right leg which had existed for eight months, with numbness in some of her fingers and the sole of one foot. She had intention tremor. The knee-jerks were well-marked, but there was no ankle clonus and no nystagmus. Vision with the right eye was $\frac{6}{9}$ and with the left $\frac{6}{6}$. The opinion given was that she was in an early stage of insular sclerosis. A year and a half later the tremor of the right hand was reported to be diminished, but the right leg dragged more. She had recently on one occasion lost all power suddenly in the right leg and to a great extent in the left. This was accompanied by a feeling of "pins and needles." A few days ago I heard that she was more helpless than ever.

I could easily multiply such cases were there time. It will be noted that there is only an imperfect resemblance of symptoms in these cases, but that is what one must be prepared to expect in this disease. The islets of interstitial myelitis which eventually become sclerosed are variously scattered in individual cases, producing therefore disorders of function referable to different parts of the frame. Considering, indeed, the morbid anatomy of the disease it is quite remarkable how much general resemblance may be found in the cases. In several the "intention tremor"—i.e., the tremulousness of the arm when a voluntary movement is undertaken—is marked; in others this is absent. Nystagmiform movements of the eyes occur in several. A history of diplopia is very common, whilst incontinence of urine is of great frequency. I look upon these symptoms as pointing to organic disease of the central nervous system. There are two others upon which, in my experience, great stress should be laid as indicative of organic disease. One is impairment of vision, with more or less atrophy of optic discs. The other is the history in the case of recovered power in a limb where this had been more or less lost, with recurrence on one or more occasions of similar paresis after longer or shorter intervals in the same or some other limb. The fact that in the course of insular sclerosis there are apt to be periods varying in length of almost or even complete subsidence of symptoms, though mentioned by Charcot and some succeeding writers, is not yet, I think, sufficiently remembered and taken into account. These intervals of exemption are sometimes long. In a lecture given here last year I showed a patient in whom there had been an interval of eleven years between her attacks. When sixteen years old she had attacks of powerlessness in the right arm, so that she used to drop things. These attacks recurred during three months and then altogether ceased. At twenty-seven years of age she had a sensation of pins and needless in the left foot and her leg dragged. When shown here she presented a typical picture of insular sclerosis.

CASE 7.—In 1877 a girl aged twenty years was brought to me with great loss of power in her legs, especially the left. A short time previously the right had been most affected. She complained also of numbness of the left hand. She was typically hysterical in manner and her moral character I was told had changed. She had marked "intention tremor,"

Hosted by Google

impaired articulation, and ankle clonus, on the strength of which symptoms I expressed the opinion that she was suffering from organic disease, probably insular sclerosis. A few months later I heard that she was quite well. Two and a half years after my examination her medical man, to whom I applied for information as to the sequel, wrote me as follows: "When last saw Miss —— she was very well. ..... I cannot help thinking that her symptoms are due to that wonderful simulator—hysteria." I heard nothing more of her till 1891 (fourteen years after her visit to me), when I was called into the country to see her. She had been bedridden for two years and presented all the unmistakable characteristics of advanced insular sclerosis.[1]

CASE 8.—A woman aged forty years lost all power in the left leg at the age of thirty-three years. After six months she recovered and was able to walk well. She remained well for four years, when the right leg began to go as the left had gone in her former attack. Three years later the left leg again lost power quite suddenly and when I saw her both legs were useless. Her case had been diagnosed, I was told, as hysteria, and she had been hypnotised for many months previous to consulting me. I found inability to write, with great incoördination of the hands, marked atrophy of the right optic disc, nystagmus, and exaggerated knee-jerks. She was evidently suffering from insular sclerosis. A month later she died from cardiac failure, probably due to invasion of the bulb by the disease.[2]

CASE 9.—A girl sixteen years of age suffered from partial loss of power in her legs and failure of coördination in them. Her condition was diagnosed as hysterical, and this appeared to be confirmed by her complete recovery in two or three months. She remained apparently well for more than five years, during which time she was in the habit of taking a large amount of exercise, walking, riding, and hunting. Then she complained one day of some difficulty in walking and three days afterwards became perfectly paralysed in the lower extremities. She lay powerless for from three to four weeks and then gradual improvement took place, and she regained strength enough to walk with support. A little later she suddenly again relapsed and became paralysed in the arms as well as the legs. I was told that the case had been pronounced to be one of hysteria and the Weir-Mitchell treatment recommended. Examination showed the existence of marked intention tremor in each arm, especially in the left, excessive knee-jerks, and slight ankle clonus. The right optic disc was atrophic. She was evidently suffering from insular sclerosis. A year later I learned that the disease had greatly progressed; there was great contracture in the legs, incontinence of urine and fæces, still further impairment of sight, with loss of memory.[3]

I can hardly lay too much stress upon the fact that intermissions of the kind shown in these cases are very common, although they are not constant, in the course of insular sclerosis. It is evident that the intervals of apparent recovery are peculiarly liable to give rise to the opinion that the loss of power has been hysterical. Here let me for a moment try to estimate the value of various symptoms as pointing, on the one hand, to organic disease and, on the other hand, to an hysterical condition. Intention tremor, if well marked, appears to hold a most important place in the diagnosis of insular sclerosis; it is true that in the hysterical there is not unfrequently a clumsiness of movement of the hand when directed towards an object (arising probably from a loss of muscular sense), but this rarely assumes the character of a rhythmical tremor. I cannot call to mind (looking back over many years) any instance in which well-marked intention tremor was observed in a case which the sequel showed to be of purely functional character.

Nystagmus or nystagmiform movements must also be considered important evidence of organic disease. It is, of course, necessary to remember that these movements are liable to occur in some other diseases, in coarse disease of the cerebellum, and of the corpora quadrigemina, in Friedreich's ataxy, and in chronic alcoholism. The presence of these must be excluded. Nor must it be forgotten that nystagmus, besides occurring in miners, may sometimes be found as a temporary and solitary symptom incapable of explanation in the present state of our knowledge. But this is extremely rare.

Ankle clonus if strongly marked is a valuable symptom of organic disease of the antero-lateral column of the spinal cord. But the phenomenon, usually in an imperfect form, may be of functional origin. It is very rare indeed, in my experience, for ankle clonus of well-pronounced character to exist in the absence of organic disease.

Of greater weight than any of these symptoms is atrophy, even though it be slight, of one or other optic disc. I have never seen this symptom in any case in which the sequel failed to confirm the organic character of the disease. Let me say here that a few years ago I showed that some degree of optic atrophy was present in the course of 43 out of a collection which I had made of 100 cases of insular sclerosis.[4]

Pallor of the disc will almost invariably be found associated with some visual defect. This may take the form of a central scotoma or of greater or less concentric narrowing of the visual field. In some cases the ophthalmoscope fails to detect change in the fundus oculi, although the size of the visual field or the acuteness of central vision is found by testing to be diminished.

In each of the two patients who have been before you there is very considerable contraction of the visual field. This concentric contraction cannot be ascertained by any means at our disposal to differ in character from that which occurs in some cases of hysteria, a circumstance which will be recognised as adding exceedingly to the very great difficulties which beset the differential diagnosis of insular sclerosis in an early stage. It may be asked why I do not lay great stress upon this condition of the visual field in my patient as a weighty argument in favour of her case being one of simple hysteria, as it was originally supposed to be. My reasons are these:—1. I have seen this concentric contraction of the visual field before in cases which were undoubtedly examples of insular sclerosis. 2. The concentric contraction is found almost as much marked in the first patient shown (about the diagnosis of whose case as one of insular sclerosis there can be no doubt) as in the second patient shown, who has presented hysterical symptoms. 3. This concentric contraction is associated with some non-symmetrical pallor of the optic discs. (I must warn you that a slight degree of pallor of the optic disc is very easily overlooked. It has to be searched for with care, but in order to avoid being unconsciously prejudiced I always examine the discs with the ophthalmoscope and come to a judgment as to their colour *before* inquiring into the visual acuteness or the extent of the visual fields.)

There is a symptom which is of very considerable value in the diagnosis of insular sclerosis and that is the state of the plantar reflex. It is a rule of almost universal application (as I have repeatedly urged for many years past) that the plantar reflex is either entirely absent or very feebly indeed expressed in almost all cases of hysterical paraplegia. If we exclude cases of gross structural disease of the spinal cord or brain, in the course of which the plantar reflex is not seldom lost, and also the not very infrequent instances of congenital absence of the phenomenon, we shall find, I think, that loss of plantar reflex points to a "functional" symptom. It may come and go in circumstances in which the presence of, at all events, any gross structural disease may be easily excluded. In patients with hysterical paraplegia the plantar reflex, entirely absent at the commencement of a course of Weir-Mitchell treatment, will be found to return as recovery takes place. In my experience the retention of the plantar reflex in a case of loss of power in the lower extremities of doubtful character affords a strong presumption that there is structural disease. The converse, however, does not apply. Although, if you observe closely, you will find that as a grand general rule cases of insular sclerosis are characterised by retention of the plantar reflex, you will now and again find one in which, at least for a while, the phenomenon is absent. It has been so in the case of the second patient shown. As I have shown you at the present time tickling the foot-sole produces retraction of the toes; but during a short period, when she was in the out-patient department, no such effect was produced. I believe this to have been a "functional" symptom occurring in the course of organic disease. It is very important to remember that this kind of complication—the occurrence of "functional" symptoms—is common in the course of insular sclerosis and must be allowed for. How greatly it increases the difficulties of diagnosis may readily be conceived.

Lastly, let me say that until such symptoms as nystagmus, diplopia, pallor of the optic disc, marked intention tremor, or

[1] Vide "On the Simulation of Hysteria by Organic Disease of the Nervous System," 1891. Since the publication of that work the patient, I am informed, has died with terrible bedsores and bladder trouble.

incontinence of urine make their appearance in a case about which doubt has existed I do not think that we can as a rule safely pronounce a diagnosis of insular sclerosis. But in a case in the history of which paresis has occurred in one or more limbs, with spontaneous recovery, and repeated recurrence of the symptom in the same or another part, after longer or shorter intervals, together with a history of amblyopia, either temporary or persistent, my experience would lead me to diagnose insular sclerosis in the absence even of the symptoms first enumerated.

A Lecture
ON
THE SPREAD OF PLAGUE.

Delivered before the Epidemiological Society on Dec 18th, 1896,

BY JAMES CANTLIE, M.B. ABERD.,
F.R.C.S. ENG.,
LECTURER ON APPLIED ANATOMY, CHARING CROSS HOSPITAL MEDICAL SCHOOL; LATE OF HONG-KONG.

GENTLEMEN,—The history of plague has been so often written that it is unnecessary for me to even sketch its devastations and distribution in pre-Christian, early Christian, mediæval, or more recent times. My remarks will be confined to an exposition of matters appertaining to the epidemicity of the disease as it has been met with during the latter half of this century, and more particularly to a description of the information gathered during the outbreak in China in 1894-6, and of the most recent evidence of its activity in the Bombay Presidency. The reasons for selecting the Hong-Kong epidemic as the basis of my dissertation are that plague was first studied there bacteriologically, and that many medical men, myself amongst the number, had ample opportunity of observing and recording the disease. Without entering into the discussion as to whether or not all epidemics styled "plague" in Biblical and mediæval literature were of the nature of the bubonic plague of recent times, there can be no doubt that since 1850 the name "plague" has been applied to a definite train of symptoms which are considered to constitute a specific disease. As we proceed it will be seen how during different outbreaks some one symptom attains a fatal pre-eminence, but not to the exclusion of others, which might at any time assume the death lead and serve to baptize the disease as "bubonic," "hæmorrhagic," "typhoidal," "pneumonic," and so forth.

During the latter half of the century the names bestowed on plague have been as follows:—1. In 1856 in Tripoli, it was known as "typhus with glandular swelling." When the disease reached the island of Chios in the same year it was called "petechial typhus analogous to that of Tripoli." 2. In Mesopotamia, where the disease was prevalent from 1856-85, and possibly up to the present day, the titles, "adynamic typhoid fever" and "intermittent fever with glandular swellings" were usual. 3 In Persia, where plague seems to be endemic since 1863, the term "hæmorrhagic fever" is used to designate a pestilence which differs from the diseases with which the Persians are familiar 4. During the years 1877-79 the Russian province of Astrakan was visited by a disease which was, and is, regarded as plague, but which was variously described as: (*a*) intermittent fever with buboes; (*b*) croupous pneumonia with buboes; (*c*) typhus with glandular swellings proving fatal by pneumonia; and (*d*) a peculiar form of mumps. That all the above-mentioned outbreaks were actually plague, a specific disease caused by a specific bacillus, will never be known; but the presumptive and clinical evidence is decidedly in favour of their being one and the same disease. 5. In Hong-Kong, where a moiety of languages obtain, the epidemic was known as:—(*a*) the "plague" or "the bubonic plague" by the British; (*b*) "la plaga" by the Spaniards; (*c*) "de peste bubonica" by the Portuguese; (*d*) "la peste" by the French; (*e*) "la pestilenza" by the Italians; (*f*) "die peste" by the Germans; (*g*) "wan-yik" by the Cantonese, the term signifying an epidemic disease of high mortality; (*h*) "yang-tsu-chwarg" in Yunnan, which, being interpreted, means bubonic disease; and (*i*) "li-tsu-cheng" in Pakhoi, where the disease has been endemic for many years. The name "black death" was never used, nor were any of the names by which it was known in Tripoli, Mesopotamia, or Persia, or Russia applied to it, although hæmorrhages, pneumonia, petechiæ, and typhoidal signs and symptoms were not wanting. Perhaps the most interesting name is that of the "rat plague," by which it is known in various parts of Asia, thereby affording additional proof, if such were needed, of the widespread infection of the rat during plague epidemics.

The name "plague," however, is not one which helps us to place the complaint in its proper scientific niche in the category of disease. The word conveys the idea of an unusual disease, attacking many persons and attended by a high mortality, but that gives it no scientific value any more than the "wan yik" of the Chinese. Were I to attempt to classify plague I would place it amongst the specific fevers and particularise it under the name of "polyadenitis" and individualise it still further as "malignant polyadenitis." It may be objected that adenitis is not always present, that many plague stricken patients die before the glands are even swollen and that therefore the name is defective; but it is needless to point out that in many diseases the most typical of symptoms are at times absent and yet the cases can be classed with their kind. To justify the prefix "poly" to the word "adenitis" it is necessary to remember that although one gland alone may be clinically apparent, most, if not all, the lymphatic glands are found to be enlarged at the post-mortem examinations. The most recent report in regard to this subject is interesting. "Thirty-three cases (22 per cent.) were received without a proper bubo. In most of these cases multiple adenitis was found, the general size of the glands being that of a lentil. In the latter stages of the disease other buboes formed in different localities and complicated the case; 90 per cent. of the cases showed swelling of the intestinal, bronchial, and mediastinal glands in different stages." [1]

The term "bubonic" so frequently applied to the disease is not so appropriate as would at first sight appear. A bubo is essentially the swelling of a gland caused by the entrance of septic materials in the tract of lymphatics over which the gland presides. This cannot be said to obtain in plague, for the so-called bubo of plague can in no sense be regarded as a sympathetic swelling, but merely the outcome of a blood poison. If it is to be classed a bubo at all it must be distinctly understood to be an "idiopathic" bubo, a true "bubon d'emblée." One never speaks of the buboes of tertiary syphilis or of scrofulous buboes. The terms may be clinically correct, but they are not in common use; they have, however, as much right to be called bubonic as the glandular enlargements in plague. With these considerations before us I would venture to name the disease "Malignant Polyadenitis" in the hopes that attention may be drawn to the naming of the disease by more competent students than myself.

Plague or malignant polyadenitis we may define as an acute febrile disease of an intensely fatal nature, characterised by inflammation of the lymphatic glands, marked cerebral and vascular disturbances, and by the presence of a specific bacillus. It is only since 1894 that we have been able to set forth a definition with precision; it is only since then that we have acquired the knowledge of a definite bacillus by which the disease can be recognised scientifically when ordinary symptoms are in abeyance. In this definition no mention is made of hæmorrhage, pneumonia, petechiæ, or carbuncles.

At the present day plague is confined to Asia, but since 1850 it has made its appearance in Europe, Asia, and Africa. The *western* limit of plague during the latter half of the century is the Canary Islands, where it raged in 1852; while its *eastern* limit is the Island of Formosa, off the coast of China, where it is now prevalent. The *southern* limit is practically the Tropic of Cancer, but the *northern* range is indefinite. Since 1850 plague has never travelled further north than Astrakan, about 45° N.; but we have it on excellent and sustained authority that Moscow, Norway, and Sweden, and latitudes as far as 60° N., have within the present century been visited by plague. All limits are, therefore, fairly definite with the exception of the northerly limit. In other words, plague has been met with from 19° W. longitude to 121° E. longitude and between 40° N. latitude

[1] Report of Dr. M. Wilm, dated Hong-Kong, May 20th, 1896.

Hosted by Google

to 19° S. latitude. Plague has never been known in the Western Hemisphere or anywhere south of 19° N. of the Equator.[2] The Basin of the Mediterranean and the strip of country which runs parallel to that sea across the Asian continent from Turkey to China may be roughly taken as its present belt during the nineteenth century, but the Mediterranean part of the belt has disappeared almost wholly within the present generation. A map of the plague-stricken districts within the last fifty years shows plague astride the Himalayas with a giant limb reaching on one side the Red Sea and on the other the shores of the Pacific.

What determines the distribution it is impossible to say. Racial distinctions do not account for it, as the Mongoloid and Indo-European races are equally attacked. Neither ocean nor air currents have aught to do with its transit. It seems to thrive in the densely packed population of Canton and in the sparsely populated semi-desert regions of Rajputana and Arabia; the elevated plateau of Thibet and the low-lying valleys of the Euphrates are equally affected. It occurs during the summer's heat and the winter's snows. In fact, no known meteorological condition has any effect upon either the genesis or the exodus of plague.

As animals are affected, it is interesting to inquire what animals are affected, what is their geographical distribution, and what share, if any, they take in its spread. The animal which above all others is known to be affected by plague is the rat; but the wide geographical area throughout which this animal is met with would seem to frustrate any attempt to determine a collateral distribution. On looking a little more closely, however, we find rats (the Murinæ) divided into two great sections—the mures, inhabiting the Old World (except Madagascar), and the sigmodontes, inhabiting the New World and Madagascar. Of the mures, one subfamily, that of the Nesokia, is met with, reaching from Palestine to Formosa across the northern part of India. The southern limit in India seems to be where the great bandicoot, or pig rat, exists, and here plague is unknown. This is the only animal which presents a habitation well-nigh corresponding to the present distribution of plague, and it is the animal above all others which is looked upon as being liable to be attacked by plague. The geographical distribution of this family of rats well-nigh coincides with the plague belt as delineated.

Pigeons are said to be severely stricken in Bombay at the present moment, but what kind of pigeon is attacked I have not yet been able to ascertain. When we have the information it will be interesting to note its geographical distribution. We have no notice from China, however, of the pigeons being attacked by plague. The part the rat plays as a distributor of plague will be dealt with later when we come to consider the relationship of animals to plague generally.

With regard to the continuity of plague outbreaks it would appear that in the plague belt the disease is ever active, now in one place and now in another. At times we find it in Arabia, then in Persia and the Himalayas, and the wave travels eastwards over Yunnan and Southern China to the sea. The disease oscillates, now east and now west, but with a fatal precision, making the slow swing of the pendulum of plague within a fairly definite area. A glance at the table giving the dates at which plague appeared in epidemic form since 1850 will confirm this. Taking the chief seats passed *en route* between the Red Sea and the Pacific we find that plague appeared as follows:—In 1850, India; 1850, China; 1853, Arabia; 1853, India; 1856, Tripoli; 1858, Mesopotamia; 1859, Tripoli; 1863, Persia; 1867, Mesopotamia; 1869, India; 1871, Yunnan; 1872, Persia; 1873, Mesopotamia; 1874, Arabia; 1876, India; 1876, Mesopotamia; 1877, Tripoli; 1877, Russia (Caspian Sea); 1879, Arabia; 1880, Mesopotamia; 1881, Persia; 1881, China (Pakhoi); 1883, Afghanistan; 1884, Mesopotamia; 1886, Persia; 1887–89, Arabia; 1890, China (Yunnan); 1893, Tripoli; 1894, China (Canton, Hong-Kong); 1895, China (Macao); 1896, China (Hong-Kong); 1896, India (Bombay); and 1896, Merv (?). A study of this table shows the continuity of the course of plague and how the eruption in one district is followed by its appearance in another. A slow traveller, it, however, stays when it comes, and unless the scenes of its visitation are well garnished it becomes endemic.

The cause of plague is the advent of a definite bacillus, and it is the life-history of this bacillus which must in future occupy the attention of bacteriologists and clinical observers. The proximity of the bacillus is at the present day known only by its effect on human beings, and, it may be, rats as well. What fosters it appears to be bad sanitation; once established time alone will stay its ravages so far as any given epidemic is concerned, but there seems every hope that improved sanitation will check its recurrences.

The *prodromata* of plague may be divided into the remote and the immediate, but I will consider them together. Time and again has it happened that before an outbreak of plague, during a period varying from a few months to several years, buboes with fever have been observed in a more or less epidemic form. In 1877 the variety of plague which infected Astrakan, previously to the serious outbreak that occurred in 1878 some 150 miles higher up the Volga, was classed as a "pestis minor." No one died from the disease *per se* and but few people were confined to bed. Should such another outbreak take place in the neighbourhood the diagnosis will be readily cleared up by an examination of the blood, the tissues, and the excretion.

I was of the belief until within the last few days that this disease—this pestis minor—was of a nature wholly apart from true plague. From Calcutta, however, the news of the discovery of a bacillus allied in every respect to the Kitasato bacillus of true plague and associated with the variety of plague known as pestis minor has altered my views, although the bacillus is stated not to possess the toxic or virulent properties of the true plague bacillus, but to be similar in all other respects. The real question at issue at present is: Is there a disease of an epidemic character, attended by a low death-rate, characterised by polyadenitis and showing in the blood and tissues a bacillus resembling the bacillus met with in typical plague (malignant polyadenitis), and yet so apart clinically that it is either a separate disease or caused by the same bacillus in a lesser or non-toxic form? In the discussion of this subject it is necessary to ask the following questions:—1. Does pestis minor occur as a precursor, as a collateral ailment, or a sequela of true plague? 2. Is it confined to the plague belt delineated in the map? 3. Has it anything to do with plague? 4. Is it a disease *per se?* Dr. Payne in the "Encyclopædia Britannica," writes as follows: "In the minor form of the disease spontaneous swellings of the glands occur chiefly in the armpits, but also in the neck or other parts, which either undergo resolution or suppurate. There is a certain amount of fever; the temperature is rarely high, but has been known to be 104° F. The duration of the disease is from ten to twenty days usually, but may be eight weeks, for most of which time the general health is but little impaired and the patient able to go about as usual. It rarely, if ever, causes death, the only fatal case at Astrakan in 1877 having been so through a complication. The disease is not obviously contagious; whether it is propagated by infection or not is unknown. It is possibly rather of a miasmatic character. This form of disease has sometimes preceded or followed severe epidemics, as in Mesopotamia (Irak) on several occasions (1873–78) and in Astrakan (1877). Its importance in relation to the origin of plague has only lately been appreciated. It might be expected that gradations would be found connecting this form with the severe epidemic form; but this appears to be not usually the case, the latter form appearing somewhat suddenly and abruptly; hence the minor form has probably often been regarded as a 'distinct' disease, even when observed in plague countries." From all hands we have evidence of such a disease—namely a pestis minor benign polyadenitis. 1. The Russian outbreak at Astrakan in 1877 was probably; nay, certainly, of this nature, the low rate of mortality being sufficient to stamp it other than true plague. It is to be noted also that the typical plague which ranged in the same province appeared, not amongst the community afflicted with pestis minor, but in a district 150 miles away, where pestis minor was unknown. 2. In Calcutta six years ago a form of fever existed among the British troops there which in all points resembled the present form of bubonic fever which exists there now—namely, fever with specific glandular swellings. 3. We have it also from Calcutta that the natives are frequently afflicted with glandular enlargements during malarial fever. 4. In the far east, from Singapore, the Straits, and along the coast of China as far as Shanghai, between the years

[2] This remark requires to be accepted with reservation, as it is reported that several cases of plague came to Hong-Kong from Singapore (2° north latitude).

Hosted by Google

1892 and 1896, we have accounts of a singular affection of the inguinal glands which occupied the attention of the Singapore and Hong-Kong branches of the British Medical Association. The correspondence was carried on between the societies, and there is no doubt the affection at both places was identical in its nature.

I am compelled to draw attention to this subject in consequence of a paper which appeared in the *British Medical Journal* of Sept. 26th, 1896, by Surgeon C. C. Godding, R.N. Surgeon Godding refers to many cases of chronic glandular swelling attended by fever and anæmia, and he gives a careful clinical account of several such cases as having occurred in Hong-Kong. This is the first notice to the profession generally of a type of ailment with which all practitioners in the far east are but too familiar. When the literature of the present outbreaks of plague comes to be written, the recorder will no doubt light upon these cases of glandular swellings given by Surgeon Godding, and take them as evidence of the association of pestis minor with the malignant type. We must, therefore, deal with them, come to what conclusions we may. When I brought the matter before the Hong-Kong Medical Society in 1893, I mentioned that I employed the term "bubon d'emblée" to designate the condition and that I had treated thirty-eight cases in thirty-two months. My account of the ailment was as follows: "A slowly developing non-venereal bubo occurring in one or other groin, attended by general weakness, anæmia, and fever. The groin glands affected are discrete at first, but gradually the swellings amalgamate and a large mass as big as half an orange or larger presents. At the end of about twenty days points of boggy softness occur, and if the bubo be left to itself the skin becomes undermined and the pus finds its way to the surface through two or three or more fistulous openings. The swelling, when cut into early, shows a peri glandular serous infiltration, and when pus occurs the gland will be found lying detached except by shreds of tissue at one or two points. The gland when cut into shows many focal points of suppuration and breaks down quite easily beneath the fingers." Surgeon Godding advocates arsenic as almost a specific, but my own treatment latterly was early incision. It is necessary to make a clean sweep of every gland that can be felt or seen, as there is a great tendency to recurrence in any gland or piece of a gland that is left. Seeing that glands, except strumous glands, are seldom excised for other diseases, I examined the records of the Government Civil Hospital in Hong-Kong in connexion with the excision of glands, and I found the following:—In 1891, 19 buboes were scraped or excised; cervical glands, 1. In 1892, I have not the record. In 1893, 27 buboes were scraped or excised. In 1894, 12 buboes were scraped or excised. 1894 was the plague year, and the list of operations is stated to be incomplete. Taking this evidence in conjunction with Surgeon Godding's and the private practitioners' in Hong-Kong and Singapore we have weighty evidence of a widespread affection, be the cause what it may.[3]

Another form of glandular idiopathic enlargement is seen in what may be styled an epidemic form in children. In the year 1891, I reported twenty-three cases at the Medical Society in Hong-Kong, and since that date cases have frequently occurred. The affection consists of an enlargement of one gland, seldom more, in the necks of children over the sterno-mastoid about the middle of its length The swelling is seen *upon* the sterno-mastoid, but it might be found to commence, were it met with early enough, in a gland on its anterior border. The disease appears infectious and is attended by feverishness. There is no throat affection, nor is the seat of the disease in the parotid. We, the medical practitioners, styled the condition for convenience sake mumps, but we all admitted that neither the parotid nor the submaxillary glands were the seat of trouble. It will be remembered that the term "peculiar form of mumps" was employed by some to designate the Astrakan disease in 1877. 6. In the years 1893-4, and since, in Hong-Kong, cases of fever of a typho-malarial type occasionally presented in the third or fourth week a general enlargement of lymphatic glands, which lasted for a week or ten days and then subsided. They were deemed interesting cases at the time, but with the fresh light thrown upon them by recent investigation, more especially the researches in Calcutta, they assume a new aspect.

[3] Europeans were mostly attacked by these buboes, being 83 per cent. of the cases operated upon.

To sum up the evidence before us it would seem—(1) that a fever with glandular enlargement, pestis minor, a "benign polyadenitis," is an established disease; (2) that it may be independent of plague or malignant polyadenitis; (3) that the two may coexist; and (4) that the one may exist independently of the other.

As to infection and contagion, direct contagion, that is, transference of the disease from the sick to the healthy by bodily contact would appear at the first glance to be an element in the transmission of plague. How otherwise can we explain the circumstance that, when a case of plague occurs in a house, those dwelling in the house and brought in contact with the sufferer are almost certain to be seized, and not only so, but few, if any, of the other inmates escape. The next in order to be seized by plague are the relatives of the sick and the visitors to the house, who, going to their own homes, set up a fresh focus of infection. Of the community, medical men, clergymen, and attendants, who are brought in contact with the sufferers, more readily acquire the disease than others who are alien to the family and house. These facts would appear to prove conclusively the contagious nature of plague. But there is another side to the argument. As long ago as 1835, when plague was epidemic in Egypt, out of ten French medical men who attended the sick only one contracted the disease. Further, we have the well-known case of Bulard during the same outbreak, who, anxious to prove his contention that the contagious nature of plague was much exaggerated, for two days wore the shirt of a patient who had died from plague. Yet Bulard did not contract the disease. More recently we have the evidence of the Hong-Kong epidemic in 1894. None of the European medical men in attendance on the plague patients, in all, some fifteen in number, were attacked by plague. Those men were freely exposed in the wards and at post-mortem examinations, yet none were infected. Further, none of the British or Italian born nurses—these were the only two European nationalities represented—were attacked by plague during 1894. But a more interesting fact still is that none of the Chinese students of the College of Medicine were attacked. For six weeks these men were on duty in turns night and day in the Plague Hospital. Eight of them acted as ward attendants and clerks throughout the period and were consequently in constant contact with the sick. A racial immunity might be claimed for Europeans, but in face of this fact it cannot hold good. If there be any truth in the acquisition of disease during an epidemic by fear or nervousness the case of these students refutes the legend. They saw that the Europeans escaped and how terribly their countrymen suffered; they had to contend with the superstitious beliefs of their country, inherited and acquired; they were breathing the same air, eating similar food, hearing daily, hourly even, of the deaths of their friends, relatives and acquaintances, yet none of them succumbed to plague. We have, therefore, two opposite conditions before us—namely, plague entering a house and seizing practically all the inmates; and, on the other hand, medical men, nurses, and native students acting as clerks and dressers escaping completely. Where, then, lies the truth of the contagious nature of plague?

As usual, there is a channel of escape from either of these two extremes of argument. The immunity above related does not extend indefinitely. The Europeans attacked during the 1894 epidemic were chiefly soldiers of the Shropshire regiment, then stationed in Hong-Kong. When plague required sanitary interference beyond the power of the local board these soldiers came forward and volunteered to help in the work of cleansing and purifying the city. The work assigned to them was of the most laborious order and they were exposed to a concentration of the contagion, for the field of their duty lay amongst the dwellings of the poorest class of Chinese who were suffering from plague. Those houses were of the vilest kind of habitation mankind is acquainted with; small, windowless, low-ceilinged, reeking with filth and excretions, they presented infection in its most concentrated form. Further, the soldiers had to use spade and shovel to dig down into the accumulated layers of dirt on the floors of the houses and throw it into the street. It was this occupation more than any other to which is attributed the infection of the soldiers. During the 1894 epidemic two of the sisters of the Italian Convent contracted the disease and died, but they were neither of them Italian born; they were both Eurasians and in very humble circumstances. In 1894, also, three Japanese medical men contracted plague, of whom one died.

Hosted by Google

The two who recovered were both considered to have inoculated themselves at a post-mortem examination on a case of plague. The facts recorded would seem to show that, during the 1894 epidemic in Hong-Kong, English practitioners and nurses enjoyed an immunity which did not extend to the Japanese medical men or to the nurses of Eurasian blood.

The evidence of the subsequent outbreak in Hong-Kong in 1896 goes to show that Europeans were much more frequently attacked than in 1894, and two of the nurses in attendance on the sick contracted plague. One of the nurses was a British-born nursing sister at the Plague Hospital, where she had been for many months. She never was ill until the very end of the epidemic, when she got a sharp attack of plague, from which, however, she fortunately recovered. The sister (Katherine M'Intosh) believes she was infected by a little child she nursed, and whom she frequently carried about in her arms. The other European nurse was an Italian-born sister in the convent, who believed she was infected in the same way—viz., by nursing and carrying about a child sick from plague. The Italian sister died from her disease. It is interesting to note that the patient from whom the English sister contracted her disease recovered, whereas the patient of the Italian sister died. Was the recovery of the English sister due to a lessened degree of infection, seeing that her patient recovered, and the death of the latter due to the extreme malignancy of the emanations from the body of the dying child? is a pertinent question. Nor is this all, for yet another sister in the convent died, presumably infected whilst nursing her companion. These three deaths seem to point markedly to contagion rather than infection as the means of spread, for although there were some 600 persons in the convent none of the other inmates were afflicted thereby.

Gathering this evidence together and trying to focus it we find that the soldiers who were affected were exposed—if there is any truth in intensity of contagium at all—to the most concentrated form of the poison. They worked not in the streets in the open air, but in reeking hovels for several hours together Intimate and prolonged contact with the contagium in an active condition seems to be the explanation of their infection. The same is to be said of the two European nurses who were seized. Both attributed their ailment to intimate and prolonged contact with a generating source—viz., a child carried in the arms not for a few minutes, but for several hours daily extending over several days. That there are, moreover, degrees of power in the contagium, even when emanating from the human body, seems to be supported by the nurse and infecting child both recovering in the one instance, and the nurse and infecting child both dying in another. Bulard sleeping in the dead man's shirt proves nothing further than that the plague-infected garment did not generate poison of an intensity sufficient to infect. The poison grew every moment more dilute, but a nurse carrying a child, throwing off contagium continuously, is an exposure of a different stamp. The immunity of the medical men and Chinese students does not annul the effect of prolonged and intimate contact as being a means of spread; for it must be remembered that the medical man "visits" only, he does not stay for a day beside one case as a relative does, nor does he sleep or eat under the same roof as does a nurse. In this way also the immunity of the Chinese students is to be accounted for. They performed their task in a newly-built, commodious, and roomy mat-shed. Freely ventilated by being raised three feet from the ground, and its lofty roof constructed so that air swept across between the side walls and the roof with large apertures in the roof itself, the chance of contracting the disease from so diluted a form was reduced to a minimum.

The practical lesson to be learned from these statements is that free ventilation, and attention to ordinary hygienic rules, lessen the chance of contracting the disease to a very great extent, not only for Europeans, but also for natives; but that all are liable to contract the disease when either from the calls of duty or wilful neglect exposure is extreme.

(To be continued.)

AWARDS FOR MEDICAL SERVICES.—Dr. J. S. Mackay and Dr. Alex. L. Curror of Kirkcaldy have been awarded by the town council £100 each for services rendered by them during the late epidemic of typhoid fever.

A Clinical Lecture

ON

PELVIC INFLAMMATION IN WOMEN.

Delivered at the Middlesex Hospital on Dec. 3rd, 1896,

BY WILLIAM DUNCAN, M.D.,

OBSTETRIC PHYSICIAN TO THE HOSPITAL; EXAMINER IN OBSTETRIC MEDICINE AND GYNÆCOLOGY AT THE VICTORIA UNIVERSITY AND AT THE CONJOINT EXAMINING BOARD FOR ENGLAND.

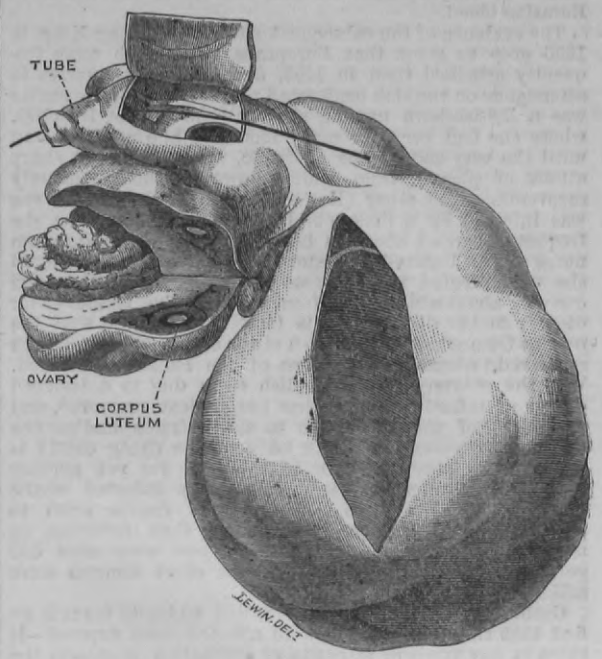
GENTLEMEN,—Pelvic inflammation in women is probably the most frequent disease which in one form or another is met with in general practice; it is often dangerous to life and always causes a great amount of chronic suffering if allowed to progress unchecked. On the other hand, if diagnosed and treated in its early stages it can often be cured. Far better still, if proper preventive measures (which we will consider presently) be adopted many women can be saved from the onset of the disease.

In the first place let me say that the manner in which pelvic inflammation has been hitherto dealt with in most text-books on the diseases of women requires complete revision. Formerly it was the custom to divide pelvic inflammation into (*a*) perimetritis or pelvic peritonitis, and (*b*) parametritis or pelvic cellulitis, to give a long string of causes for each disease, and to describe separately the symptoms, physical signs, and treatment of each. But nowadays with the help of the light which has been thrown on the subject by performing abdominal section for diseases of the ovaries and tubes the situation is completely changed. And what do we learn? Why, that parametritis (pelvic cellulitis) is rarely met with except after parturition, and that pelvic peritonitis (perimetritis) is in the vast majority of cases associated with, and caused by, pre-existing disease in the Fallopian tubes or ovaries, or both. This being so, when discussing pelvic inflammation in women we must consider not only perimetritis and parametritis, but also disease of the tubes (salpingitis, hydrosalpinx, pyosalpinx, and hæmatosalpinx) and of the ovaries (ovaritis and ovarian abscess).

I particularly want you to remember that, except after parturition, pelvic inflammation in its widest sense is due to infection extending along the Fallopian tubes *from the uterus*. A precisely analogous state of things is met with in disease of the appendix vermiformis. The peritonitis, cellulitis, and abscesses which complicate an appendicitis are due to an infection inside the appendix which passes through its walls to the surrounding peritoneum and cellular tissue. In exactly the same manner does an infection of the Fallopian tube cause similar results: with this difference, that the infection, instead of having to extend through the walls of the tube (as in the case of the appendix), finds an easy exit in the first instance through the abdominal ostium. The cause, then, of pelvic inflammation is almost always either septic or specific infection.

Septic infection is in the great majority of cases the result of parturition, though a few cases may be due to the use of sponge or laminaria tents or to operations performed on the uterus with dirty instruments; this latter is not very likely to occur in these days of aseptic surgery. Bernutz analyses 99 cases of peritonitis as follows: 43 occurred in puerperæ; 28 occurred after gonorrhœa; 20 occurred during menstruation; and 8 were traumatic—viz., 3 owing to excessive coitus, 2 from syphilis, 2 from the use of the sound, and 1 from the use of the vaginal douche. Specific infection from gonorrhœa is accountable for 28 of the 99 cases; but in my opinion the 20 cases in which menstruation is given as a cause of peritonitis had in addition disease of the tubes, probably of gonorrhœal origin. So that almost all the cases of peritonitis occurring in women, apart from labour, are most likely secondary to specific infection from gonorrhœa. I do not go so far as to say that any man who contracts gonorrhœa and gets completely cured of it before he marries is in the least likely to infect his wife; but, from personal knowledge, I can assure you that men who consider themselves well and who are "passed sound" by their medical men, but who probably have a slight and occasional gleet which the excitement of marriage renders virulent, do sometimes infect their wives with gonorrhœa,

Hosted by Google



which, unless promptly and vigorously treated, may give rise to untold suffering and completely ruin a woman's health and happiness. These unfortunate cases are doubtless met with more frequently in the lower orders, but are not confined to them by any means. I may here briefly mention two cases which occurred in my practice in 1896.

CASE 1.—A woman aged twenty-four years, who was perfectly well up to marriage, began two months later to suffer from dysmenorrhœa, somewhat profuse menstruation, and an inter-menstrual yellow discharge. On examination I found the upper half of the vagina in a state of granular vaginitis; the uterus was tender on bimanual examination and a muco-purulent discharge was seen exuding from the os uteri, around which was some erosion. No thickening of either Fallopian tube could be felt. On questioning the husband he at once told me that he had suffered from a severe attack of gonorrhœa two years previously. This was followed by a gleet, which, however, for six months before marriage was very slight in amount and only occurred at intervals, so his medical man told him he might safely marry. After marriage the gleet became more abundant. It was evident the wife had gonorrhœal endometritis, and vigorous measures were at once called for so as to prevent the disease spreading to the tubes. Under anæsthesia I dilated the cervix up to No. 14 Hegar and thoroughly scraped away the endometrium with the flushing sharp curette; next I swabbed out the uterine cavity with iodised phenol, and then packed it with a long, thin strip of iodoform gauze; finally the vagina was packed with iodoform gauze. These plugs were allowed to remain for forty-eight hours undisturbed; they were then removed, the vagina was irrigated with a 1 in 3000 perchloride of mercury solution, an iodoform pencil was passed into the uterine cavity, and the vagina was again filled with tampons of iodoform. Subsequently for a fortnight the vagina was douched twice daily with a similar solution and a couple of iodoform plugs were passed into the upper part of the vagina. In two months the patient was perfectly cured and she continues so. The husband is now under treatment by a surgeon who found a stricture of the urethra, and of course coitus will not be resumed until the patient is quite well, as he fully understands the great risk his wife would otherwise be exposed to.

CASE 2.—The patient was a woman who married last Easter. I saw her six weeks later when she said that a week after marriage she began to suffer from pelvic pains, a yellow discharge, pain on micturition, and great pain on coitus. She had been treated all this time by her husband's medical attendant, who gave her medicine, but no local examination was made or suggested. I at once insisted on examining her and found she had urethritis, vaginitis, and endometritis. She went into hospital without delay and I carried out the same treatment as in Case 1 and with a like satisfactory result. On sending for the husband he admitted that he contracted gonorrhœa in January last, but said his medical man told him he might marry when he did. He also admitted having had a urethral discharge the day after marriage; this he attributed to taking a good amount of wine at the wedding breakfast! I explained to him the danger his wife ran if he resumed intercourse before he was completely cured and advised him to consult a surgeon. This, I am sorry to say, he neglected to do, the result being that his wife again came to me a month later with recurrent vaginitis, for which she had a second time to enter the hospital. I need hardly add that I reproached the husband in the strongest terms with his brutal conduct.

If, then, pelvic inflammation is usually due, as I maintain it is, to infection carried from the uterus through the tubes, let us shortly consider what happens. A good deal depends on the virulence of the infection. In mild cases the only result may be a "catarrhal" inflammation of the lining of the tube, in which the secretion is serous in character, and this may escape into the uterus or it may even pass through the abdominal ostium into the peritoneal cavity without setting up peritonitis; or in addition there may be cellular infiltration into the coats of the tube, causing it to become greatly thickened, even to the size of one's finger (chronic interstitial salpingitis), but without any pus formation. These are the cases in which, if the co-existing endometritis be cured, a return to perfect health may be reasonably looked for. In other cases of catarrhal inflammation the ends of the tube are closed, the tube becomes more or less distended, giving rise to a hydrosalpinx, or, whilst the abdominal ostium is closed, the uterine end of the tube remains patent and the distended tube at intervals discharges its contents into the uterine cavity (intermitting hydrosalpinx). Fig. 1 is a typical illustration of a specimen of this condition which I removed from a patient some years ago.

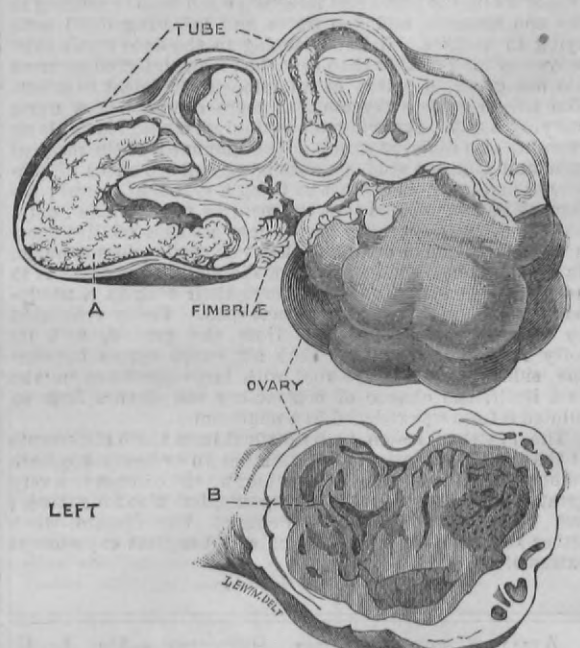


FIG. 1.

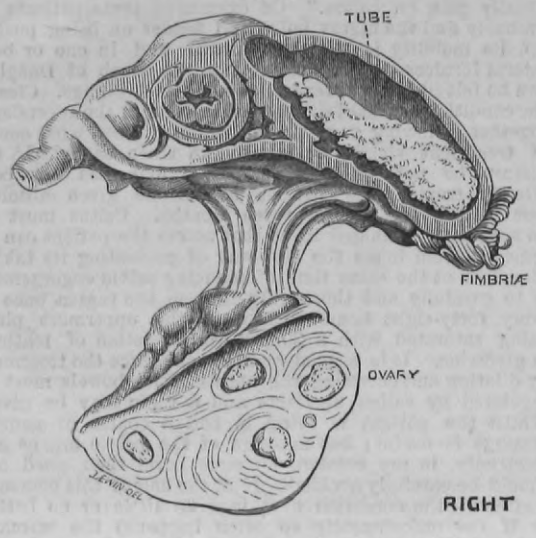
Intermitting hydrosalpinx: left Fallopian tube and ovary. The tube is greatly distended and the coats are thinned, the abdominal ostium is closed, and the uterine end (through which a bristle is passed) is patent. The ovary is enlarged and adherent to the tube. It contains a corpus luteum and a blood clot.

In more severe cases, however, a purulent salpingitis sets in; the pus may escape for a time into the uterus, but sooner or later a little passes through the abdominal ostium, giving rise to more or less severe pelvic peritonitis, with all its

FIG. 2.



Left ovary and tube. The ovary is enlarged, adherent to the tube, and full of blood (B). The tube is distended with inspissated tuberculous pus (A).

Hosted by Google

dangers and results. In these cases of purulent salpingitis the ostium becomes closed by peritonitic adhesions and the pus may escape through the uterine end of the tube, but more often this also gets closed. Pus accumulates in, and distends, the tube, giving rise to pyosalpinx. A rare condition is where the tube becomes distended with cheesy, tuberculous pus. Figs. 2 and 3, which illustrate this condition well, are taken from a case on which I operated in 1890. The patient, aged twenty-two years, had been married two years and had never been pregnant. The catamenia began at fifteen years of age and were always accompanied by pain and clots, but especially so since marriage. When the abdomen was opened the peritoneum was seen to be studded with rice-like bodies. Both the tubes and the ovaries were full of yellow, cheesy pus, and were everywhere matted

FIG. 3.

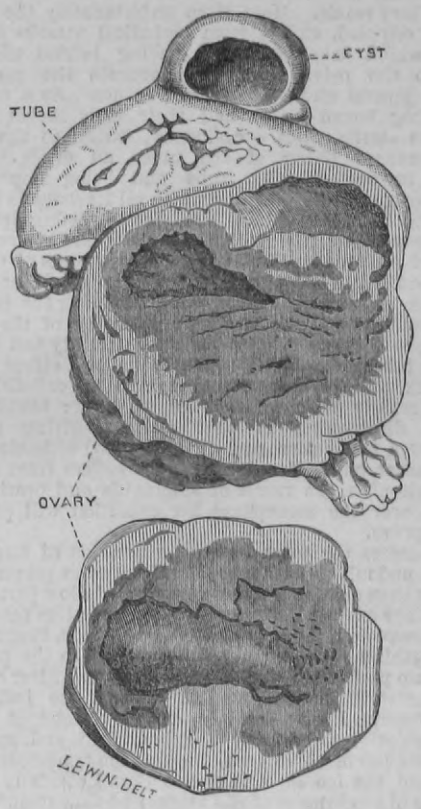
Right ovary and tube. The ovary is twice the normal size, containing deposits of cheesy pus. The tube is distended with similar material.

down by adhesions, making removal very difficult. The patient made an excellent recovery and was in good health several years after the operation.

When the tube leaks into the peritoneal cavity peritonitis follows, and this may be either (*a*) serous, (*b*) plastic, or (*c*) suppurative; it may be quite localised or affect the whole pelvis, or even in very severe cases may become general. Usually it is limited in extent, the ostium of the tube becomes closed, and the ovary is matted to the tube; then ovaritis follows or an abscess may be formed in the ovary. (Fig. 4.)

The form of peritonitis most often met with is the plastic, where lymph is thrown out, matting the parts together; and in severe cases, where this matting is general, it feels on vaginal examination as if the uterus were fixed in a mass of plaster-of-Paris which had been poured in from above. After a longer or shorter time most of the effusion is absorbed, but adhesions are left, and these bind the various pelvic organs together in all manner of ways. Sometimes the adhesions are few and easily broken down when abdominal section is performed; at other times they are so firm, dense, and universal that it is only after a prolonged and dangerous operation that the ovaries and tubes can be shelled out and removed. Indeed, in some few cases their removal has to be abandoned.

As I have already pointed out, it is after labour that pelvic cellulitis or parametritis occurs; especially when there has been extensive laceration of the cervix, an exudation takes place into the cellular tissue of one or other broad ligament, giving rise to a unilateral swelling which pushes the uterus over to the opposite side and which, though usually absorbed, may form an abscess that bursts externally above Poupart's ligament but may open into the bowel, vagina, or bladder.



With regard to the symptoms and physical signs af acute pelvic inflammation I need say little. The sudden onset, pyrexia, pelvic pain, and the mass to be felt either surrounding the uterus or to one side of it cannot well be mistaken. But when we have to diagnose chronic disease of the tubes and ovaries associated with slight peritonitis the case is by no means so simple. The chief symptoms are (*a*) pain, (*b*) hæmorrhage, and (*c*) yellow discharge.

The pain varies; in catarrhal salpingitis it is slight, as there are no pelvic adhesions; but in purulent salpingitis and ovaritis (especially when the ovary and tube are matted together) there is more or less constant pain in the back and iliac fossæ, extending down one or both thighs, and aggravated by coitus, walking, or jolting in a carriage.

Hæmorrhage is pretty constant in these cases in the form of menorrhagia; the periods recur every two or three weeks, are more profuse, painful, and accompanied by clots. In the intervals of the periods there is a muco-purulent uterine discharge.

The physical signs vary of course with the condition present. In simple salpingitis it will probably be impossible to detect anything wrong with the tubes, but where the inflammation has been severe and of some duration one or both tubes can be felt as thick and tender cords running out from the sides of the uterus. Let me advise you to always make a digital examination per rectum when the bowels have been emptied, as you can thus learn far more than by a vaginal examination. In many cases the ovaries can be felt enlarged, tender, and prolapsed into Douglas's pouch. In other cases a more or less rounded mass will be felt to one or other side of the uterus, which latter is displaced somewhat to the opposite side, is tender on pressure, and its

FIG 4.

Chronic peritonitis. The ovary and tube are matted together; the ovary (shown in section) is much enlarged and full of blood; the tube is dilated.

mobility is impaired. This is the condition which until recent years has been described as a "pelvic cellulitis of the broad ligaments." As a matter of fact it is nothing of the kind, for, as already mentioned, pelvic cellulitis occurs rarely except after parturition. In these cases the tube is thickened, perhaps contains some serum or pus, the ovary is enlarged, and cystic, and both tube and ovary are matted together by adhesions forming a tumour which appears larger to the fingers on bimanual examination than it really is found to be when the abdomen is opened. In other

Hosted by Google

cases, when one or both tubes are distended, the condition is easily recognised provided the tube develops the typical shape—an elongated cystic swelling constricted at intervals and extending outwards from the uterus. Even when the tube has this shape one cannot positively say what is the nature of the fluid inside it, for a pyosalpinx may exist without any irregular rise and fall of temperature. As a rule, however, the symptoms are fewer and less severe in a case of hydrosalpinx than in one of pyosalpinx. Not infrequently the dilated tube develops a rounded shape (owing to adhesions) and then it cannot be distinguished from an ovary distended with pus or cystic. Indeed, I never like to give a positive diagnosis of the nature of any pelvic swelling until after I have opened the abdomen. A point to remember in examining a pelvic tumour is that care is necessary lest it be ruptured. About eighteen months ago I was suddenly summoned to the hospital one afternoon and told that whilst examining a woman in the out-patient department the clinical assistant felt a cystic tumour in the pelvis suddenly disappear and the woman became faint. She was at once admitted. On my arrival an hour later she had rallied and I could find no sign of a ruptured cyst; still, as the resident medical officer assured me there had been one I at once opened the abdomen and found about a pint of clear fluid which had escaped through a rent in a thin-walled ovarian cyst. This I removed and the patient recovered without a bad symptom; fortunately for her the cyst contents were not purulent.

Now what is the prognosis in cases of chronic pelvic inflammation? If the tubes be only affected with catarrhal inflammation, provided the endometritis be cured, perfect recovery may result. More often unfortunately the patient becomes crippled, suffers from periodical attacks of peritonitis, which usually subside leaving behind still more injury to the pelvic organs; sometimes the peritonitis becomes general and a fatal result ensues. As a rule, the tubes being bound down and their ends sealed up the woman is sterile; but occasionally, owing to the injury to the mucous lining of the tubes, an ovum becomes arrested in one or other tube, and being impregnated there an extra-uterine pregnancy with all its dangers follows. If one or both tubes be dilated into a hydrosalpinx the patient may have fairly good health but is liable to recurrent attacks of peritonitis. If, however, the contents of the tube be pus, or if there be an ovarian abscess, there is far greater danger, as peritonitis is sure to recur, rendering the patient a chronic sufferer, whilst also she runs the risk of the collection of pus bursting into the peritoneal cavity and causing a rapidly fatal end. In a few cases the pus, either from a pyosalpinx, ovarian abscess, or suppurating cellulitis, may burst externally or into the bowel, vagina, or bladder, and continue discharging in that manner, giving rise to hectic fever, emaciation, and (if untreated) ultimate death. On the other hand, if a patient who suffers from chronic pelvic peritonitis, the result of salpingitis and ovaritis, can be tided over the menopause her condition will probably much improve.

Lastly comes the most important question of treatment. It being undoubtedly true that in these cases prevention is far better than cure, and as so very many follow parturition, we nowadays exercise the greatest care ourselves (and insist on the nurse doing likewise) that our hands, instruments, and everything that comes into contact with the patient's genitals are perfectly aseptic. If a day or two after delivery the temperature rises above 100° F. and the lochia are at all offensive I give an intra-uterine douche of a 1 in 5000 perchloride of mercury solution night and morning, and if after two or three such douches the temperature does not fall and the lochia become odourless I carefully curette the whole of the interior of the uterus and thus remove every possible source of infection there; after curetting another douche is given and a twenty-grain iodoform suppository is passed well into the uterine cavity. These measures can be carried out with the patient lying on her left side and without an anæsthetic.

With regard to pelvic inflammation occurring apart from labour or an abortion, and remembering that it is almost always preceded by an endometritis, it behoves us to most carefully investigate all cases in which married women complain of pelvic pain, pain on coitus, increased menstruation, and an inter-menstrual yellow discharge, for assuredly if we find only an endometritis (without involvement of the tubes) we can by adopting the vigorous treatment I have already described cut short the disease and save the woman from untold future misery. If, however, we first see the case when acute pelvic peritonitis is actually present, then the condition must be treated in the usual way by giving a saline purge to start with, followed by hot vaginal douches at a temperature of from 108° to 112° F. three times a day; these douches must be given whilst the patient is lying down and several quarts of water used each time. If sedatives are required I prefer morphia suppositories. Hot fomentations or poultices applied to the abdomen are soothing and at all events do no harm. The acute attack usually subsides in ten or fourteen days, leaving the uterine appendages more or less damaged.

We are often consulted by patients who give a history somewhat as follows. "After the last confinement (which may have been months or years previously) they had an attack of 'inflammation' and since then have suffered with pains in the pelvis, excessive and painful menstruation, with a yellow discharge in the intervals of the periods, also usually pain on coitus." On examining these patients we probably find the uterus bulky and tender on being pushed up, its mobility is less than normal, and in one or both lateral fornices (and extending into the pouch of Douglas) can be felt ill-defined, tender, and elastic swellings. Clearly the condition is that of disease and matting of the appendages together following a pelvic peritonitis. Now, what course of treatment should be adopted in these cases? If the disease be not of long standing and has not been already treated the patient should be given absolute rest in bed for two or three months. Coitus must on no account be indulged in, so that unless the patient can be removed from home the best way of preventing its taking place and at the same time of reducing pelvic engorgement is to carefully and thoroughly tampon the vagina once in every forty-eight hours with wool, the uppermost plugs being saturated with a 20 per cent. solution of ichthyol in glycerine. It is a good plan to commence the treatment by dilating and curetting the uterus. The bowels must be regulated by saline aperients and a tonic may be given. Whilst the patient is lying in bed a course of general massage is useful; but massage of the pelvic organs and electricity, in my opinion, do more harm than good and should be carefully avoided. If at the end of this course of treatment the condition of things be little or no better, or if (as unfortunately so often happens) the woman's state of life prevents her from having such a prolonged rest, there are only two courses open—either the patient drags on her life more or less of an invalid and in suffering, or she elects the wiser course of having abdominal section performed and the diseased parts removed. The mortality from this operation, when performed by a skilled operator, is not more than 3 per cent. The risks of the operation and the fact that in all probability both tubes and ovaries will require removal must be fully explained to the patient and her friends, and their full consent to allow the operator a free hand—so that he can use his own judgment as to how much requires removal—must in all cases be obtained in writing before any operation is entered upon.

The results are in most cases very satisfactory, the patients losing their constant pain, and although it sometimes takes months for them to regain robust health I have never yet had a patient who regretted undergoing the operation. If operation be absolutely refused and the patient be in a position to afford the expense a six weeks' annual course of the mineral waters and mud baths at one of the German watering-places—such as Schwalbach or Kreuznach—will sometimes prove beneficial in relieving pain and promoting the absorption of inflammatory pelvic products, so that life may be rendered fairly tolerable until the menopause sets in, after which the pelvic conditions may be expected to cause less trouble. But, no matter whether the patient be wealthy or poor, if a cystic swelling of the tubes or ovaries be detected, as it is impossible to say definitely whether the contents be purulent or not, it is our duty to urge the necessity of abdominal section being performed without delay.

ST. JOHN AMBULANCE ASSOCIATION.—His Royal Highness the Prince of Wales, President of the St. John Ambulance Association, has sanctioned a grand ambulance *fête* and demonstration to be held at the Crystal Palace in May or June next in commemoration of Her Majesty's long reign, under the personal patronage of Her Royal Highness Princess Christian, President of the Norwood and the Great Western Railway Centres, and other members of the Royal Family

ACTINOMYCOSIS AND MADURA DISEASE.

BY EDGAR M. CROOKSHANK, M.B. LOND.,
PROFESSOR OF COMPARATIVE PATHOLOGY AND BACTERIOLOGY, KING'S COLLEGE, LONDON.

(WITH COLOURED PLATE.[1])

Is human actinomycosis a rare disease in this country, or are there many cases lost sight of under a variety of names? I am anxious to draw the attention of the general practitioner to this disease, by indicating its clinical manifestations, and more especially by pointing out how easily it may be diagnosed by means of a bacteriological examination, as this may lead to the recognition of many cases in private practice, to their publication, and ultimately to the determination of the extent to which actinomycosis exists in this country. I propose to add a short account of madura disease, which should be studied in connexion with actinomycosis, as there are several points bearing upon their relation to each other which require further elucidation by careful observation and experiments. The readiness with which actinomycosis may be mistaken for other morbid conditions which resemble it and the absolute necessity for a microscopical examination are illustrated by many of the early descriptions of this disease both in man and in cattle. In 1845 Langenbeck of Kiel made notes of a case of vertebral caries and prepared drawings of peculiar bodies present in the pus from an abscess. The drawings were published many years afterwards and there can be no doubt that these particles were typical ray-fungi. In 1848 Lebert received from M. Louis some pus of a thick, almost gelatinous, constituency from the thoracic wall of a man aged fifty years. The patient was suffering from a pulmonary affection cancerous in nature. The pus contained a number of little spherical bodies of a slightly greenish-yellow colour, each about the size of a pin's head. They were readily crushed between two glass slides, and on examination with a power of fifty diameters they were found to consist of a soft, connective substance and many wedge-shaped corpuscles arranged in a radiating manner. Lebert figured these bodies and thought of helminthic débris, but he searched in vain for echinococci and cysticerci. Rivolta of Turin claims to have been the first to discover the ray fungus in a bovine case. As early as 1868 he published a paper on this subject, while Perroncito, who studied the sarcomata of cattle, claims to have observed the micro-organism in 1863. Hahn of Munich in 1870 detected it by microscopical examination, for he states that in a bovine case of "wooden tongue" he found characteristic organised structures which he provisionally regarded as a species of mould fungus. Robin in 1871 both described and figured most accurately the bodies which we now recognise as "ray fungi." They were found in two or three cases in the pus of deep-seated chronic abscesses in man, and were described as yellowish grains composed of elements swollen at one end and tapering off at the other, arranged in a regular series radiating from a common centre, which consisted of granular matter. Bollinger, in 1876, pointed out that actinomycotic growths occasionally occurred on the upper and lower jaws of cattle. These growths either started from the alveoli of the back teeth or from the spongy tissue of the bone, and by increasing in size loosened the teeth. In their progress they destroyed bone, muscles, mucous membrane, and skin. After some time they frequently broke down, forming ulcers, abscesses, and fistulæ; while in some cases tumours were formed which might attain the size of a child's head. Actinomycosis in man was first described as such by Israel in a paper published in 1878, and Ponfick was the first to clearly recognise the identity of the disease in man with that occurring in cattle. Israel, in addition to the club-shaped elements, recognised and described a central core of fine filaments. In a work which he published in 1885 the various cases which had been observed up to that time were described. From this time onwards numbers of cases in man have been recognised with the aid of the microscope, and the publications of Bostrom, Moosbrugger, and my reports to the Agricultural Department of the Privy Council may especially be referred to. Altogether some hundreds of cases have been diagnosed, but very few of these have been contributed by English practitioners. In England, Dr. T. Acland was the first to recognise the disease by microscopical examination of the liver after death, and Dr. H. Taylor was the first to demonstrate the presence of the ray fungus during the life of a patient. Shattock found specimens in museums which, though bearing other names, were really from cases of actinomycosis. Among the English cases I may also mention those described by Dr. Skerritt, Mr. Eve, Dr. Ransom, Dr. Fairweather, Dr. Poore, and Mr. Malcolm Morris. I shall refer more in detail to some of the comparatively recent English cases in describing the various manifestations of the disease.

Though actinomycosis in cattle has long been known in this country, it, as in man, was mistaken for other diseases or received popular names. Indeed, to many the disease is still familiar under the names of wens, clyers, scrofulous abscesses, polypus, lymphoma, cancer of the tongue, lumpy jaw, bone cancer, bone tubercle, osteo-sarcoma, and fibro-plastic degeneration of bone; so that until about eight years ago, when my Reports were published, actinomycosis was not generally recognised as a common disease of cattle in this country, in spite of the interest excited by the work of Fleming, to whom is due the credit of being the first to recognise the fungus in a bovine case. In 1887 there was a disease prevailing in Norfolk, and in the following year outbreaks of the same disease were reported in Essex, Hertfordshire, Cambridgeshire, and Middlesex. In the Norfolk outbreak on one farm 8 per cent. of the cattle were suffering from wens or sitfasts, which I found on microscopical examination to be produced by actinomycosis. In all similar specimens which I have received from different parts of England and Scotland, as well as from the colonies, I have been able to demonstrate the presence of the ray fungus. I also met with the disease in other forms, including a case of pulmonary actinomycosis, with grape-like growths on the pleura, which had been regarded as tuberculous. In Australia tumours in the upper and lower jaw commonly occur in cattle, and were attributed to scrofulous inflammation, or designated cancer or lumpy jaw, but a microscopical examination has revealed their true nature. In America also the disease was known as lumpy jaw, and is prevalent. Mr. Casewell, State Veterinarian, examined cases microscopically, and on one farm in Yates City, where there were eighty head of cattle, no less than sixteen were found to be suffering from actinomycosis. Mr. Casewell reported to the Board of Live-stock Commissioners for the State of Illinois that the disease was common in nearly every county in that State and that in his opinion it was increasing. In one instance 109 animals suffering from actinomycosis were slaughtered. But is the disease really spreading in America, or is it that by increase of knowledge and by more careful observation more cases have been brought to light? And as regards actinomycosis in man in England, may we not well ask whether the disease is really a rare one, or is it not rather that many cases are still overlooked through want of discrimination with the microscope? With a view to obtaining further information with regard to the human cases in this country I will proceed to point out the various ways in which the disease has been found to manifest itself in cattle and in man.

MANIFESTATIONS OF ACTINOMYCOSIS.

I.—ACTINOMYCOSIS OF THE DIGESTIVE SYSTEM.

(*a*) *Of the upper and lower jaw.*—In cattle actinomycosis commonly attacks the upper and lower jaw and is frequently associated with carious teeth. The growth extends and invades the neighbouring cavities and sinuses, destroying the tissues with which it comes in contact, expanding the bones into thin plates or reducing them to the appearance of pumice stone. Quite recently I received the head of a Sussex steer in which the lower jaw was diseased on both sides (Figs. 1 and 2). On dissecting away the soft parts it proved to be a most characteristic case of so-called osteo-sarcoma. The teeth on both sides were carious. In man also the fungus may gain access through carious teeth, or wounds or fistulæ of the jaw, and very possibly by inflammatory processes in the pharynx and tonsils. The disease attacks the lower jaw most frequently. The tumour

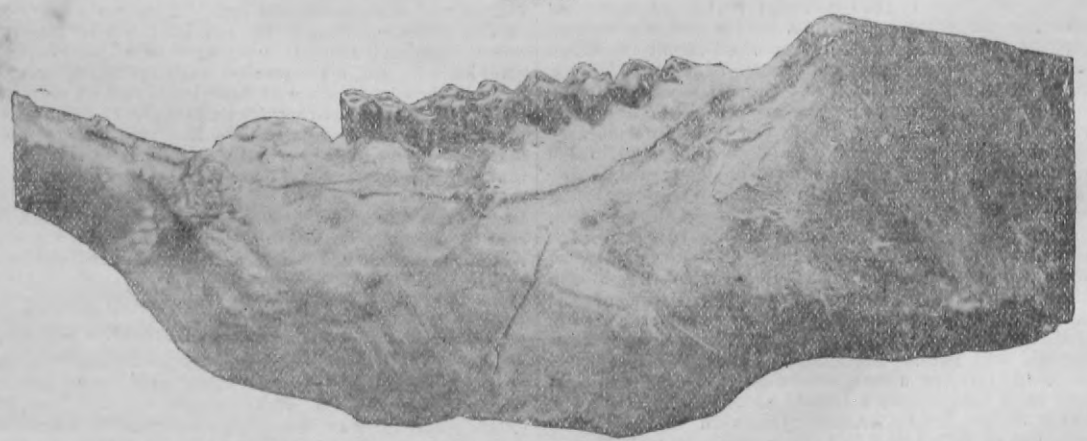
[1] This article is based upon a Post-Graduate Lecture delivered at King's College on Oct. 30th, 1896. The coloured plate and some of the photographs are reproduced from the article on Actinomycosis in 'Bacteriology and Infective Diseases."

Hosted by Google

is found in close connexion with the bone or in the submaxillary or sub-mental region and also in the præ-tracheal region. It occurs, though rarely, in the interior of the bone. In a case described by Israel, that of a woman aged forty-six years, there was a small tumour about the size of a cherry attached to the external surface of the lower jaw, with an opening through which a probe could be passed into the bone. The tumour was incised and scraped away, and a cavity discovered in the bone, admitting a small sharp-spoon.

FIG. 1.

Actinomycosis of the lower jaw of a Sussex steer (in an early stage). (About one-third the natural size.)



Later, a further operation was performed; the periosteum was detached, the cavity of the bone enlarged and the contents scraped out, consisting of granulation tissue, fragments of bone, and the yellowish fungi. At the bottom of the cavity the fang of the canine tooth was found. No return of the growth occurred.

The first cases of human actinomycosis observed in America were connected with the jaw. In 1884 Dr. Murphy described two cases at Chicago. The first patient was a woman aged twenty-eight years. Two weeks previously she had suffered from severe toothache, with swelling in the throat and great pain in swallowing. It disappeared after poulticing, but she was again attacked with toothache and a swelling appeared on the angle of the jaw on the left side. The mouth could not be opened without difficulty; the tonsil was much enlarged and pus was set free on incision. She still suffered from toothache and a small swelling now occurred on the left side of the neck below the jaw. She had several carious teeth. The swelling, which was about the size of a walnut, was punctured and a drainage-tube inserted; a creamy-looking discharge containing yellow granules continued to escape, but the swelling and induration increased. A further operation was decided upon. The carious tooth was removed, and a probe passed into the alveolus showed a communication with the external wound; the angle of the jaw was chiselled away and the alveolus scraped out. Iodoformed gauze was applied and the patient recovered.

The second case was that of a man aged eighteen years who had also suffered with severe toothache and swelling at the angle of the jaw. On examination a carious tooth was noticed. The swelling was well marked and there was fluctuation; it was as large as a pigeon's egg and situated below the jaw. When punctured, thick creamy pus escaped containing the fungi; the sinus was scraped out and in ten days the wound was healed. Another swelling appeared and this was treated as before and the patient recovered.

The peculiar feature of growths in this region is their apparent migration. Israel states that in one case a tumour occurred on the alveolar process, close to carious teeth, and later was close to the edge of the jaw in the sub-maxillary region. Thence it disappeared, and a large swelling formed below the hyoid bone, and after this had been incised and

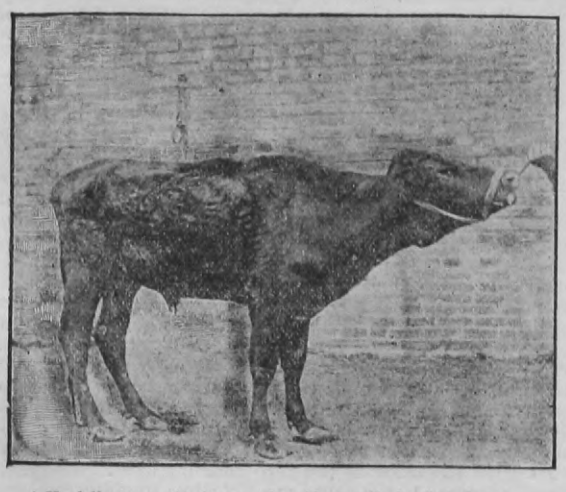
had healed an abscess formed above the clavicle. In other cases the disease has been described as extending from the alveolar process to the temporal bone or the base of the skull, destroying bones and even reaching the brain; or the growth may descend by the spinal column, implicating the vertebræ and travelling and pointing in various directions.



(*b*) *Of the lips, gums, buccal mucous membrane, and palate.*—In cattle we find the disease occasionally appearing in the form of nodules, wart-like growths, or ulcers on the lips, gums, buccal mucous membrane, and palate. The nodules and ulceration of the palate were particularly well marked in a specimen submitted to me for examination under suspicion of being the result of a severe attack of foot-and-mouth disease.

(*c*) *Of the tongue.*—In cattle, actinomycosis of the tongue shows itself in the form of nodules or wart-like patches under the mucous membrane, with a special tendency to ulcerate from the irritation of the teeth. These nodules may extend into the deep muscles and often collect in rows more or less parallel to the superficial muscular fibres. Complete transverse sections of the tongue, double-stained, readily show this arrangement even to the naked eye. Induration of the tongue results from secondary interstitial glossitis. I have only in one case found a distinct tumour of considerable size embedded in the substance of the tongue. It was about as large as a small Tangerine orange, and more or less completely isolated from any surrounding neoplasms.

(*d*) *Of the pharynx.*—In the pharynx I have found the disease in cattle in the form of polypoid growths. In one case there was a large growth about the size of a cricket ball which by interference with deglutition produced great emaciation and ultimately death from asphyxia (Fig. 3).

(*e*) *Of the intestines.*—Small nodules about the size of a pea may be found in the human intestine in the sub-mucous tissue and in the mucous membrane itself. They soften and form ulcers with undermined edges, the base reaching the muscular layer. They may undergo cicatrisation, but generally the disease extends through the peritoneum to the abdominal cavity, and perforates the bladder or the intestines or makes its way through the abdominal wall. Symptoms are either absent or not characteristic. The fungus may sometimes be found in the evacuations or by exploratory puncture. In a human case under the care of Chiari death with general marasmus took place at the age of thirty-four years after an illness of two years' duration. The mucous membrane of the intestines was found at the post-mortem examination to be almost entirely covered with whitish patches raised in the centre and covered with yellow and brown granules closely adherent to the subjacent tissues.

FIG. 3.

A Norfolk steer with large polypoid growth in the pharynx producing emaciation; and a "wen" in the præ-tracheal region.

FIG. 4.

Section of liver from a case of actinomycosis in man.

(*f*) *Of the liver.*—The liver has been found to be the seat of the disease in several cases in man. The actinomycotic growths have a characteristic naked-eye appearance from their peculiar honeycombed structure (Fig. 4). The spaces between the fibrous trabeculæ are full of caseous matter, in which the more or less spheroidal masses of the fungus are embedded. In museum specimens which have been for some time preserved in spirit the contents of the loculi may have fallen out and the honeycombed appearance is then much more marked than in recent specimens. In Dr. John Harley's well-known case, which was recognised after death as one of actinomycosis, the patient had been admitted to St. Thomas's Hospital with a very painful tumour, about the size of an orange, projecting forwards from the left hypochondrium. The skin covering it was distended, shining, and pale, and the swelling was very painful on pressure. After death it was found that a number of tumours were scattered throughout the liver, and on examining sections under the microscope Dr. Acland discovered the ray-fungus. Subsequently Mr. Shattock examined similar specimens in the museum of St. Thomas's Hospital, and in two cases with honeycombed abscesses the ray-fungus was detected. Dr. Skerritt and Mr. Eve have both met with this disease of the liver.

I think it is extremely probable that cases of actinomycotic invasion of the digestive system not infrequently occur in general practice and are attributed to other causes. I am

Hosted by Google

supported in this belief by the fact that Dr. W. Ransom has published an account of no less than eight cases which have been brought to his notice within the last six years in the Nottingham district alone. In five instances the mouth was probably the seat of invasion and in all the digestive tract was affected. These cases included one of actinomycosis of the orbit, two of actinomycotic perityphlitis, one of actinomycosis of the head and neck, two of actinomycosis of the neck, one of actinomycosis of the cheek, and one of actinomycosis of the rectum and prostate. In the same year Dr. Fairweather recorded a most interesting case of actinomycosis commencing in the vermiform appendix.

II.—ACTINOMYCOSIS OF THE RESPIRATORY SYSTEM.

(*a*) *Of the nasal cavities.*—In cattle the disease may occur in the nasal cavities either primarily or as the result of extension of a growth from the lips or from the pharynx.

FIG 5.

Actinomycotic tumour of the trachea.

(*b*) *Of the larynx, trachea, and bronchi.*—In cattle polypoid growths, either sessile or pedunculated, arise primarily in the larynx, trachea, and bronchi, or occur secondarily by extension from the tissues in the neighbourhood. I have had one specimen submitted to me in which the disease had invaded the mouth, travelled downwards by the lymphatics, and ultimately developed a polypoid growth in the interior of the trachea (Fig. 5). In one recorded case in man the

FIG. 6

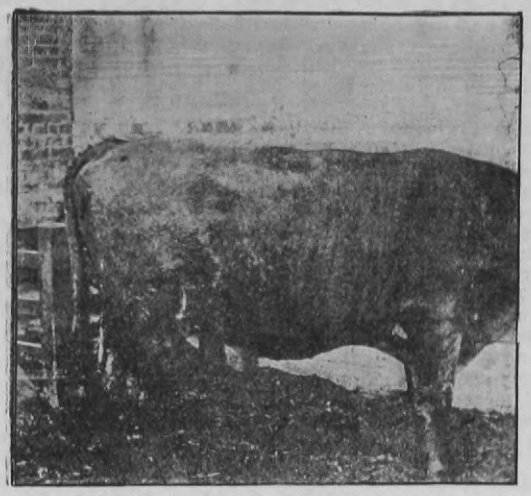
Actinomycotic nodules from the pleura (bovine).

disease existed for seven years and was localised to the bronchi. The fungus was detected in the sputum by microscopical examination.

(*c*) *Of the lungs.*—Actinomycosis of the lungs is of especial interest from its liability to be mistaken for tuberculosis. When there are actinomycotic nodules in the lungs of cattle and actinomycotic grape-like masses on the pleura (Fig. 6) this mistake may be most readily made. In man the course of the disease in the lungs may be thus described. The spores of the ray-fungi are inhaled and pass into the bronchioles and alveoli, where they produce proliferation of round cells, which undergo fatty degeneration. The resulting patches of peri-bronchitis or pneumonia become yellowish-white, suppuration and hæmorrhage from the capillaries follow, and small cavities result, containing pus cells, fat granules, blood, and the fungi. In the neighbourhood of the new growth there is compression of the alveoli, and ultimately the formation of a dense stratum of connective tissue, separated from the cavities by a lining of granulation tissue containing the characteristic fungus. The symptoms are usually obscure; but the sputum may contain the fungi, which are often visible to the naked eye. The apices of the lungs are not, as a rule, affected. There is considerable clinical resemblance to chronic phthisis; cough, night-sweats, pallor, shortness of breath, and hæmoptysis are symptoms common to both. The existence of these symptoms with the absence of tubercle bacilli in the sputum would lead to the suspicion of actinomycosis, and the detection of the fungus is positive evidence as to the nature of the disease. In the second stage the symptoms are more characteristic. The disease spreads to neighbouring parts and pleurisy commonly supervenes. This extension may involve the peri-pleural tissues. Thus the disease may follow the præ-vertebral tissues, descend behind the insertion of the diaphragm, and point as an ordinary psoas or lumbar abscess; it may perforate the diaphragm and reach the abdominal cavity. Peritonitis or sub-phrenic abscess may then result. In some cases adhesions have formed, and the disease has extended to the liver or spleen, or other abdominal organs. The disease may also extend forwards in the direction of the anterior mediastinum and the pericardium. The primary affection of the lung becomes of secondary importance. Grave symptoms occur—hectic fever, night-sweats, rigors, and marked pallor. In the third stage the disease comes to the surface, either over the chest or in the neighbourhood of the dorsal or lumbar vertebræ; a swelling appears of a livid colour, and if punctured no fluid escapes, but if allowed to make its own way to the surface the skin gives way, a muco-purulent discharge mixed with pieces of the growth escapes, and the fungi can readily be recognised.

I have said that the ray-fungi may be detected with the naked eye, and I may illustrate this by a reference to the case recently described by Dr. Vivian Poore. The patient had come under the care of a medical man in the country with all the symptoms of effusion into the right pleura. Paracentesis was performed and in the pus the little yellowish particles were observed. By a microscopical examination the diagnosis of ray-fungi was readily confirmed.

I have indicated how readily this disease may be mistaken for tuberculosis, and the case recognised by Mr. H. Taylor, and subsequently described at length by Dr. Douglas Powell, Mr. Godlee, and Mr. Taylor, is of special interest in this connexion, for there was a strong family history of phthisis. This case was briefly as follows. A boy aged nine years was admitted to the Brompton Hospital for pleurisy. He had a hacking cough, dyspnœa, and hectic temperature. Over the fifth interspace there was a soft swelling. A piece of rib was excised by Mr. Godlee and a large soft mass was felt within the chest walls which was thought to be of sarcomatous origin. Mr. Taylor examined microscopically a fragment of the growth and detected the ray fungus, which was also readily found in the purulent discharge. About four months afterwards the boy died and the case was found at the post-mortem examination to be one of primary invasion of the lungs with extension to the peri-pleural tissues. All other organs appeared to the naked eye to be free from the disease, except the liver, in which there was a small actinomycotic abscess.



Hosted by Google

A more recent case also very strikingly illustrates the resemblance to tuberculosis and was recorded in THE LANCET.[2] A patient had been suffering with symptoms of acute pleurisy. Paracentesis was performed, but the fever continued. No tubercle bacilli could be found in the scanty sputum. Later the patient came under the care of Dr. Heusser of Davos. Slight infiltration of the right upper lobe and a cavity in the right lower lobe were diagnosed, and to the surprise of the physician in charge instead of tubercle bacilli typical ray-fungi were found in the expectoration.

III.—ACTINOMYCOSIS OF THE SKIN AND SUBCUTANEOUS TISSUES.

The skin and subcutaneous tissues are a favourite seat of this disease in cattle, producing the so-called wens or clyers

FIG. 7.

A Norfolk steer with extensive actinomycotic ulceration of the skin of the flank.

so commonly seen in the fen country. A wen is first recognised as a small tumour the size of a marble or walnut, which increases in size sometimes with great rapidity, and breaks down and discharges its muco-purulent contents through the inflamed and ulcerated skin (Figs. 7 and 8); or

FIG. 8.

A Norfolk steer with a "wen" about the size of an orange in front of the throat.

it may go on increasing, and form a large compact growth the size of a child's head (Fig. 9). These growths when excised, hardened, and cut, have the characteristic honeycombed appearance, produced by the interlacing bands of fibrous tissue, which form a spongy structure, from the interstices of which the fungus tufts and thick yellowish pus have for the most part dropped out. Actinomycotic tumours of the face in man sometimes correspond with "wens" or "clyers," and, as in cattle, they may discharge

FIG. 9.

A Norfolk heifer with a large "wen" in the parotid region.

through the skin and the opening close or a fistula result. They differ in their tendency to form burrowing abscesses instead of recognisable tumours. In this respect they recall chronic inflammation rather than sarcoma-like growths. An interesting case of this kind was brought before the Pathological Society of London by Mr. Waring and reported in THE LANCET.[3] The patient had been admitted to the hospital for a swelling of the cheek, which increased in size and burst into the mouth with discharge of purulent fluid. The swelling subsequently re-appeared and an incision was made at a fluctuating spot. In the pus which escaped the ray fungus was detected.

IV.—ACTINOMYCOSIS OF THE NERVOUS SYSTEM.

Both in cattle and in man, tumours are very rarely found in connexion with the nervous system. They may occur primarily or as the result of extension of the disease from neighbouring parts. Dr. Delépine has met with and fully described a most interesting case in man of an actinomycotic tumour of the brain.

V.—ACTINOMYCOSIS OF THE REPRODUCTIVE SYSTEM.

The disease has been very rarely found to occur in man in the organs of reproduction. I have only met with one case in cattle, and this was the result of an extension to the scrotum of actinomycotic ulceration of the skin in the vicinity.

VI.—UNCLASSIFIED CASES OF ACTINOMYCOSIS.

In addition there are a number of recorded cases presenting very varied symptoms and anatomical relations in which it has not been possible to satisfactorily determine the path of infection or to account for the seat of invasion. I need only refer in illustration of these cases in man to one reported in THE LANCET.[4] This case was under the care of Dr. Marten of Adelaide. There was an ill-defined swelling near the great trochanter, associated with weakness, fever, night sweats, and insomnia. The swelling was incised and the discharge contained abundance of the ray-fungus. Later an incision was made almost the whole length of the thigh and various sinuses scraped out and a portion of the vastus externus which was studded with nodules was excised. In cattle the disease has been found in a few cases localised in the udder.

BACTERIOLOGICAL DIAGNOSIS.[5]

Careful examination of pus from a case of actinomycosis in man will reveal to the naked eye little yellowish-white or yellow bodies, which a casual observer might mistake for grains of iodoform. On collecting some of the discharge in a test-tube and holding it between the light and the eye the

Hosted by Google

tufts of fungi appear as brownish or greenish-brown grains, embedded in a muco-purulent matrix. On spreading some of the discharge on a glass slip the largest tufts of the fungus are found to be about the size of a pin's head. They have a distinctly sulphur-yellow colour by reflected light, but appear of a yellowish or greenish-brown tint by transmitted light. With a sewing needle or a platinum wire flattened at the end into a miniature spatula the grains can be readily picked out of the purulent discharge, transferred to a clean slide, and gently covered with a cover-glass. Examined with an inch objective they have the appearance of more or less spheroidal masses of a pale greenish-yellow colour. On removing the preparation from the microscope, and gently pressing down the cover glass with the finger, the grains flatten out like specks of tallow; and on again examining with the same power they are found to have fallen apart into a number of irregular and sometimes wedge-shaped fragments of a faintly brown colour, affording a characteristic appearance. By preparing another specimen and covering it with a cover-glass without completely flattening out the grains, the spherical, oblong, and reniform masses of which they are composed can be recognised with a $\frac{1}{6}$ in. objective as rosettes of clubs. If the grains consist of typical rosettes and be merely covered with the cover-glass and examined without being flattened out between the cover-glass and the slide they will recall to mind, on focussing alternately the centre and the periphery, the appearance of the capitulum of a composite flower. The central portion appears to consist of spherical forms; these are the extremities of the component elements, and as we focus the edge of the rosette these elements are seen laterally and their characteristic club-form is readily distinguished. The central portion may be flattened against the cover-glass, and as the individual clubs vary considerably in size, the appearance of an irregular mosaic is then produced. By examining the peripheral part of a rosette with a $\frac{1}{12}$th in. objective, and especially after pressing the grains into a thin layer, with or without the addition of a drop of glycerine, the characteristic clubs are most readily demonstrated and the most varied shapes observed. In some cases the clubs will be found to be bifid at the extremity; in other cases there are lateral offshoots or daughter-clubs. Here and there will be found clubs closely pressed together like a bunch of bananas, and in other cases the broken-off pieces have a palmate form. In many cases the clubs are divided by transverse fission into two, three, or more segments. As a rule the clubs are regular in shape and about equal in size, while a few are conspicuous by their length. In other parts of a preparation the clubs are replaced by long, slender forms, which are sometimes transversely divided into a number of short links. With suitable illumination many clubs are seen to taper off into slender filaments. In addition there are free filaments, which are twisted, branched, and sometimes spirilliform. Many of the clubs are composed of layers differing in their refractive power and many have the appearance of a central channel. There are also in the same preparation small, highly refractive bodies, fat granules, granular detritus, round cells, pus cells, and sometimes blood corpuscles. The grains differ, as a rule, from those from a bovine source, in the absence of a sensation of grittiness so often transmitted to the finger when pressing the cover-glass upon them, and in the slightly greater tendency of the tufts to retain their compact form. By teasing the grains in a drop of water on a slide, and examining the preparation with a $\frac{1}{6}$ in. or a $\frac{1}{12}$ in. objective, the explanation of this is forthcoming; for by this process the clubs are gradually washed away and a central core remains, which is composed entirely of a dense network of fine filaments. This can readily be observed by using a small diaphragm, and it will be found that the rosettes of clubs are now replaced by tangled masses, having some resemblance to miniature tufts of cotton-wool. These filaments constitute the delicate network which is seen in tissue-sections stained by the method of Gram. This can be readily verified by making a cover-glass preparation of the grains and staining by that method. The clubs in fresh specimens have a faintly greenish tint, and in form and arrangement are quite characteristic and easily recognisable.

The fungus in cattle may in the same way be detected with the naked eye in the muco-purulent discharge or in a scraping from the cut surface of a growth. The tufts of the fungus vary in size under different circumstances, from that of a grain of fine sand to that of a pin's head. If the pus or scraping be spread out on a slide and examined against a dark background the grains appear to be white or yellowish-white in colour; but if examined by transmitted light they appear distinctly brownish. On pressing the cover-glass on the slide the grains readily flatten out, being of a soft, tallowy consistency; or in the process of gently pressing the cover-glass on the slide with slight lateral movement a distinct gritty sensation is transmitted to the finger, owing to the presence of calcareous matter. On examination with a low power the fungus will be recognised in the form of irregular patches scattered over the field, which might readily be regarded as collections of granular *débris* of a brownish or yellowish-brown colour. On examining with a higher power, spherical, ovoid, or reniform bodies are to be seen which are either typical rosettes of clubs, or granular masses with here and there a club-shaped body at the periphery. Pus cells, round cells, fat granules, and minute spherical bodies may also be distinguished. By teasing out the grains in water, and pressing them apart between the slide and cover-glass, we find that the central portion is composed, as a rule, of a structureless core; but the core may be composed of the delicate filaments which are found in cultures and in the fungus from man. Calcareous material, if present, may readily be demonstrated by the action of acids. It will be found that on the addition of dilute hydrochloric, nitric, or acetic acids the calcareous deposit is dissolved while the clubs are not affected, and even with the addition of the strongest acids the only result will be to dissolve out the calcareous matter and clarify the tufts of the fungus, the form of the clubs being still recognisable. Permanent preparations may be made by mounting the fungus in glycerine.

The fungus in stained specimens.—Although the ray-fungus can be detected without any staining process there may sometimes be doubtful appearances, and then sections or cover-glass preparations should be made and stained by the method of Gram and with eosin or with orange-rubin (Plate, Figs 1 and 2). The filaments in human cases can be readily recognised, and this is of value, as it forms an additional means for the diagnosis of the disease. In combination with eosin or with orange-rubin we have a test that is as characteristic and useful as that employed for staining sputum for tubercle bacilli. The discharge, scraping from a growth, sputum, or the isolated fungus is squeezed between two cover-glasses, which are then slid apart; they are allowed to dry, passed through the flame in the ordinary manner, and then stained. The cover-glasses can be cleared in clove-oil, the excess of clove-oil being removed by gentle pressure between pieces of blotting-paper, and then the preparation can be mounted in balsam and rendered permanent. On examination of these specimens the masses of filaments will be found to be stained blue and the tissue elements pink. The filaments vary very much in extent and character in different preparations. In some cases there are masses of short threads, which are some straight, others sinuous, or twisted, and sometimes branched. In other parts the field is occupied by very short, straight, or curved and sometimes even spiral fragments; in others, again, there are comparatively long strands. On examination with a high power and with careful illumination some filaments will be observed to be moniliform, while others are provided with a terminal oval body. There are also free elements resembling cocci which are stained blue, and represent the spores of the organism. If orange-rubin be used instead of eosin the clubs will be more deeply stained. Both methods enable one to determine the exact relation of the threads to the club-shaped bodies. The threads are stained blue and the clubs crimson. In the younger clubs the protoplasm of the thread can be traced into the interior of the club. (Plate, Fig. 3 *b*) In some of the older clubs stained with orange-rubin the central portion takes a yellowish stain, and in others the protoplasm is not continued as a thread, but is collected into a spherical, ovoid, or pear-shaped mass (*b*). In others, again, irregular grains, stained blue, are scattered throughout the central portion. The sheath of the thread is stained pink; and the protoplasm, stained blue, fills the sheath, or consists of small spherical and irregular grains, giving a distinctly beaded appearance.

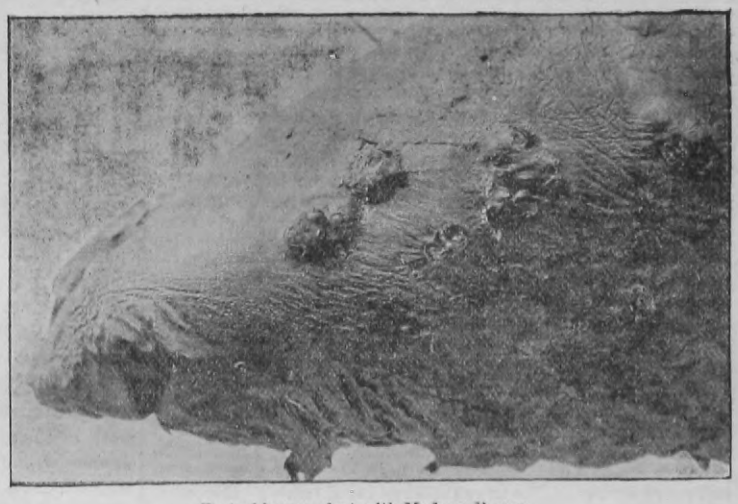
The effect of various reagents should be tried upon the isolated grains. The grains are picked out of the pus and transferred to watch-glasses containing strong potash, xylol, and benzole. If returned to a slide and covered with a

Hosted by Google

cover-glass the clubs are found unaltered. Water or weak potash washes away the clubs and the filaments become easily distinguished; ether and strong acids have no effect upon them. Corallin soda, Hanstein's violet, and iodine zinc-chloride fail to give any particular reaction. Hoffman's blue stains the clubs, but without bringing out any structural details which could not be observed in the unstained specimens.

Appearances of cultures.—Boström, Wolff, Israel, Paltauf, and others have shown that actinomyces can be cultivated in the ordinary nutrient media I have carried on a series of cultivations for some years on glycerine agar, gelatine and in milk, in broth, and on bread-paste, and potato, in order to observe the changes which take place and to study the variations which I found in the appearance of sub-cultures. In my experience the actinomyces after a few days on glycerine agar at the temperature of the blood, forms little, white, shining, moist colonies, which may remain stationary or increase and coalesce. In a week or ten days, sometimes earlier, and sometimes after several weeks, the cultures turn a bright yellow colour, but some remain white; others, again, have a tinge of pink and others are yellowish-brown (Plate, Figs. 7 and 8). After a time a powdery efflorescence makes its appearance on the surface of the culture, which may be either yellow or white in colour. The culture may go on increasing, spreading over the surface of the medium, and retain its yellow colour, or it may turn black, partly or completely, while the agar is coloured brownish-black. Cultures have a peculiar sour smell; the variations in cultures were all proved, by careful testing by sub-cultures, to be due to the growth of the actinomyces under varying conditions of soil, temperature, and the supply of air. On microscopical examination the cultures are found to be composed of dense masses of fine branching filaments (Plate, Fig. 5 *a*). Filaments with slight terminal enlargements may occasionally be seen, but typical rosettes of clubs are not to be found. These appearances are only obtained when the fungus is growing in the living body. The stage of efflorescence corresponds with the breaking-up of the filaments into masses of ovoid spores, singly, and in chains often closely resembling streptococci (Plate, Fig. 6). Gelatin is slowly liquefied. Wolff and Israel cultivated actinomyces on raw and boiled eggs and claim to have succeeded by inoculation in the peritoneal cavity, in producing the disease in rabbits and guinea-pigs in the form of tumours of the peritoneum.

Life-history of streptothrix actinomycotica.—The life-history of the micro-organism may be summed up thus. The spores sprout into excessively fine, straight, or sinuous, and sometimes spirilliform threads which branch irregularly and sometimes dichotomously. The extremities of the branches develop the club-shaped bodies. The clubs are closely packed together so that a more or less globular body is formed with a central core composed of a dense mass of threads. The threads can be differentiated by the method of Gram into an external sheath and protoplasmic contents. The club-shaped body externally appears to be mucilaginous, while internally it is continuous with the protoplasm of the thread. It is difficult to say what changes, if any, occur in the club-shaped bodies. Spores and young fungi are taken up by wandering cells and conveyed to a distance from the parent fungus, and thus fresh centres of growth are established.



MADURA DISEASE.

Mycetoma, or Madura foot, is a chronic local disease, attacking the hands and feet, and having considerable resemblance to actinomycosis. It is a disease of tropical climates, and is commonly known as the fungus-foot disease of India. A small tumour forms on the hand or foot, which after a year or two suppurates and bursts, leaving one or more sinuses, from which peculiar black particles, or white or pinkish roe-like bodies, are discharged. The disease in the foot may commence in the big toe and spread upwards, involving the leg as far as the knee, and even the thigh. In a typical case, the foot is enlarged and painful, and later there are several sinuses from which a purulent and blood-stained discharge can be expressed containing the characteristic particles. (Fig. 10.)

According to Bocarro[6] all early growths are superficial. Dissection of the growths during an operation, or sections made through the diseased tissues after excision or amputation, show that the disease generally begins in the loose cellular tissue, usually the subcutaneous tissue, and thence extends along the sheath of muscles and tendons to other soft tissues, and finally to the bones. There are several facts in connexion with the causation of the disease which are of great interest when the disease is compared with actinomycosis in cattle. Bocarro states that the disease originates in wounds, sores and pricks of thorns, and that the points of the thorns of the Acacia Arabica have been found embedded in the diseased parts. The disease is common among the agricultural class, and in 90 per cent. of the cases observed in the Hyderabad Civil Hospital it occurred in the hands and feet. Dr. Vandyke Carter was the first to point out the resemblance of the pale particles to actinomyces.[7] He described a mycelial fungus and named it chionyphe Carteri.

Dr. Kanthack pointed out that if portions of the growth were placed in ether or chloroform, and afterwards well washed in caustic potash, small rounded bodies were left which showed rays under the microscope closely resembling the appearances in actinomycosis, and that the reaction of the fungus to staining reagents was identical with actinomyces.

FIG. 10.

Part of human foot with Madura disease.

Dr. Hewlett, under my directions, examined sections from a specimen of the disease in the foot, which I had received from Surgeon-Major Hatch, I.M.S., and found both filaments and clubs. These observations were published in THE LANCET of July 2nd, 1892. Dr. Boyce and Dr. Surveyor examined a number of cases and carefully studied the black and white varieties of the disease. In the black variety the particles were found to vary greatly in size, from that of a grain of gunpowder to that of a marble. If the particles were boiled for from a few minutes to one hour in concentrated caustic potash and then transferred to distilled water the brown colouring matter was removed and a mycelial fungus could be seen. This fungus consisted of large radiating and branched hyphæ, like those of a species of aspergillus or mucor. Sections of the white, fish-roe bodies showed, usually in the centre, numerous small, reniform, deeply-stained masses, surrounded by a radiate zone, with the presence of dwarfed, club-like elements resembling actinomyces. I am of opinion that the presence of the coarser septate mycelium of the black variety may be attributed to a mixed infection. Vincent in Algiers (1891–1893) succeeded in cultivating a micro-organism and showed that it was a new species of streptothrix. He published a very full account of his researches, illustrated with

[6] THE LANCET, Jan. 5th, 1895.
[7] THE LANCET, Feb. 13th, 1886.

Hosted by Google

a coloured plate, in the *Annales de l'Institut Pasteur*, March, 1894. In the same year Dr. Boyce forwarded to the civil hospital, Hyderabad, a number of glycerine-agar tubes for inoculation and these Dr. Keith and Dr. Bocarro inoculated with particles from fresh specimens of both the black and white varieties of Madura disease. From these inoculations Dr. Boyce and Dr. Surveyor were unable to cultivate the black fungus, but Dr. Boyce succeeded in obtaining one tube with white particles which was almost free from contamination and from this tube he succeeded in isolating a streptothrix. This fungus was similar to the streptothrix which Vincent had cultivated from a case of the white variety of the disease in Algiers.

Streptothrix Maduræ.—Vincent states that the streptothrix at first grew scantily in the ordinary culture media and in such liquids as Colin's solution. In broth, at the end of about a fortnight, there is a limited growth composed of small, round, greyish masses, and in sub-cultures the growth becomes more abundant. The little colonies float in the clear liquid when the tube is shaken and subside to the bottom when the liquid is at rest, while some adhere to the sides of the tube. They may be very small or attain the size of peas; after two months they acquire a reddish tinge. Later, on the surface of the liquid, there is a white efflorescence composed of spores. The streptothrix grows well in slightly acid infusions of hay or straw, the proportion of hay to water being 15 grammes to the litre. Vegetable infusions, made with carrots, turnips, and potatoes (20 grammes to 1000 of water), also are suitable media. The streptothrix grows at the temperature of the room, but best at 37° C. and with free access to air. Inoculated in the depth of gelatine there is a scanty growth in the track of the needle and on the surface; but it grows best in a nutrient medium, composed of infusions of hay or potato 100 c.c., gelatine 9 grammes, glycerine 4 grammes, and glycose 4 grammes. Gelatin is not liquefied. Ordinary nutrient agar is not a very favourable medium, but glycerine-agar and glycose produces an abundant growth of circular, projecting, shining colonies, slightly yellowish-white, which later become pink or bright red. When the colonies are numerous they remain small, but isolated colonies grow rapidly; they are depressed in the centre or umbilicated, and the central part remains white while the periphery becomes red. Later the culture loses its colour and becomes a dull white. The growth is very adherent to the surface of the jelly and very tough—almost horny. The streptothrix can be cultivated in milk and slowly peptonises it. It cannot be grown on blood serum or egg. On potato, on the fifth day at 37° C., there are little prominent colonies, slowly increasing. After a month the growth acquires a pale rose colour, which gradually increases and changes to orange or dark red. The colour is most intense on acid potato, and after a time an efflorescence or whitish dust appears on some of the colonies, consisting of spores. The growth is hard and friable. Rabbits, mice, guinea-pigs, and a cat were inoculated subcutaneously with particles from the disease or with cultures; but only a local nodule was produced, which after a slight increase subsided. Nocard confirmed these results. Intra-peritoneal and intravenous and subcutaneous inoculations in guinea-pigs, rabbits, pigeons, fowls, dogs, and sheep were negative; and no trace could be found of the cultures in any animal subsequently killed and examined. According to Bocarro, though fresh particles from the disease inoculated in rabbits and dogs gave negative results, inoculations of cultures in guinea-pigs, rabbits, monkeys, and rats produced a local tumour of slow growth, which on section had the character of the inoculated material.

From these experiments we must conclude that the disease has not been proved to be transmissible to the lower animals by either inoculation of the diseased tissue or of cultures of the streptothrix; and the exact relation to the disease of both the mycelial fungus and the streptothrix require further investigation. It must also be borne in mind in investigating the origin of Madura disease and actinomycosis that closely allied species of streptothrix have been isolated from air, soil, pus, and the contents of the stomach, and from a disease in cattle known in France as *farcin de bœuf*. For an account of these species I must refer to the researches of Gasparini, Sauvageau and Radais, Doria, Lehmann and Neumann, Gruber, Dunker, Rullmann, and Nocard.

DESCRIPTION OF COLOURED PLATE.

(Reproduced from Bacteriology and Infective Diseases.)

FIG. 1.—From a section of a portion of an actinomycotic growth removed from a boy during life. The tissue was hardened in alcohol and cut in celloidin. The section was stained with Gram's method and orange-rubin. × 50.

FIG. 2.—From the same specimen. A mass of extremely fine filaments occupies the central part of the rosette. Many of the filaments have a terminal enlargement. The marginal part shows a palisade of clubs stained by the orange-rubin. × 500.

FIGS. 3 and 4.—From cover-glass preparations of the ray-fungus teased out of the new growths produced by inoculation of a calf with pus from a boy suffering from pulmonary actinomycosis. Stained by Gram's method and orange-rubin. The threads are stained blue and the clubs crimson (*a* and *b*). In the younger clubs the thread can be traced into the interior of the club. In some of the older clubs the central portion takes a yellowish stain and in others the protoplasm is not continued as a thread, but is collected into a spherical or ovoid or pear-shaped mass. In others, again, irregular grains stained blue are scattered throughout the central portion. × 1200.

FIG. 5.—From a pure culture of actinomyces on glycerine agar. (*a*) A mass of entangled filaments, (*b*) branching filaments. Gram's method. × 200.

FIG. 6.—From a similar but older cultivation. (*a*) Chains of spores simulating streptococci, (*b*) a filament with spores. Gram's method. × 1200.

FIG. 7.—Pure cultivation of actinomyces on the surface of potato, showing a luxuriant sulphur-yellow growth composed of entangled masses of filaments and of spores. After three months' growth.

FIG. 8.—Pure culture from the same series on glycerine agar. In this case the culture remained perfectly white. The jelly was coloured reddish-brown. After fifteen months' growth.

NEUROLOGICAL FRAGMENTS.

BY J. HUGHLINGS JACKSON, M.D. ST. AND., F.R.S.,
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL AND PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

(Continued from THE LANCET *of Dec. 12th, 1896.)*

No. XVII.

CERVICAL FRACTURE-DISLOCATION CASES.—DESTRUCTION BY COMPLETE TRANSVERSE LESION OF THE CERVICAL CORD OF INTRINSIC AND EXTRINSIC ELEMENTS OF THE LOWEST LEVEL.—PARALYSIS "AT" AND PARALYSIS "BELOW" THE LESION.—MUTILATION OF THE NERVOUS MECHANISMS OF THE "FOUR SYSTEMS" (THERMAL, CIRCULATORY, RESPIRATORY, DIGESTIVE). — INTRA-CENTRAL INHIBITION.

I HAVE spoken[1] of the great number of symptoms in cervical fracture-dislocation cases and of their diversity; the complexity of the symptomatology is obvious. Besides, there appear during the course of the cases two complicating factors. High supervenosity from inefficient respiration and great heat will, so to say, traverse that part, the main part, of the symptomatology which is not, properly speaking, *caused by*, but is indirectly consequent on, the local negative lesion; more specifically, high supervenosity and great heat will over-stimulate at least some of the citerior centres and probably some of the ulterior centres of the lowest level. Here is an important matter; blood which is highly supervenous will strongly stimulate the respiratory (medulla) centre and the cardio-inhibitory (medulla) centre; it will (vide *infra*) act on the intestines; and it will stimulate sweat glands or their centres or both; these agencies will make the symptomatology vary in different stages. Now for the second complicating factor. The imperfect action of the organs of each of the "four systems" will no doubt complicate (directly or indirectly) the action of the organs of the other three systems. To give a very simple example of this kind of complication: distension of the abdomen (digestive system) will impede the action of the diaphragm (respiratory system) and will thus render the patient's breathing still more inefficient than it already is from the paralysis of his intercostal muscles. I shall in this Note for the most part ignore these two complicating factors.

The local crush of the cord destroys both intrinsic and extrinsic elements of the lowest level. For ease of exposition I will speak as if but one segment of the infra-phrenic cervical region was destroyed; fibres passing through the segment are destroyed at the same time. First for the effect of the injury on the proper elements of the segment. There is destruction of two anterior and of two posterior horns (some motor and sensory centres of what I called[2] the homologous series of centres of the lowest level) and of their

[1] THE LANCET, Dec. 12th, 1896.
[2] THE LANCET, Feb. 16th, 1895.

Hosted by Google

interconnecting fibres; these four centres and their interconnecting fibres are intrinsic elements of the lowest level. Now for fibres passing through the segment: some of them are intrinsic, others extrinsic of the level. There is destruction of fibres connecting higher (citerior) centres of the level with lower (ulterior) centres of it; there is, for example, destruction of fibres connecting the (medulla) respiratory centre, a superior centre of the level, with costal motor centres of the level (centres of the homologous series), for movements of the intercostal muscles; such fibres, since they interconnect centres of the level itself, are intrinsic elements of it.[3] Now for destruction of other fibres also passing through the segment which are extrinsic elements of the level; I mention some of them. There is destruction of fibres from ulterior motor centres of the level as they pass through the segment on their way, not to citerior centres of the lowest level, but to centres of a higher level of the cerebral sub-system; these are fibres of the pyramidal tract, fibres extrinsic upwards to motor centres of the middle level (Rolandic region). There is destruction of fibres of the direct cerebellar tract, sensory fibres extrinsic upwards to the cerebellum.[4] There is destruction of fibres of Goll's column and of Burdach's column, fibres extrinsic downwards from, respectively, the gracile and cuneate nuclei to the periphery.

I will illustrate more particularly, and with some recapitulation, the difference between destruction of intrinsic elements and destruction of extrinsic elements of the lowest level; both kinds of the elements to be dealt with are parts of what is morphologically the spinal cord; the former (centres) are elements of the anatomico-physiological community which I call lowest level; the latter (fibres) connect motor centres of this community with centres of a higher level.

There are two *kinds* of motor paralysis in the cervical fracture-dislocation case. There is (1) to use an elliptical expression "the motor paralysis at the lesion," from destruction of certain anterior horns of the segment crushed (intrinsic elements of the level); consequent on destruction of these lowest motor centres the comparatively few muscles they should innervate *are cut off from the influence of the whole of the central nervous system.* This paralysis, using clinical language, now rather old-fashioned, is "spinal paralysis" as certainly as is that in cases of progressive muscular atrophy (Duchenne-Aran type) or that in anterior polio-myelitis. There is (2) the motor paralysis from cutting across fibres of the pyramidal tract on their way through the segment crushed (fibres extrinsic upwards from ulterior motor centres to motor centres of the middle level, Rolandic region); most of the motor paralysis in the cervical fracture-dislocation case ("the motor paralysis below the lesion," another elliptical expression) is owing to the severance of these fibres; here the muscles concerned *are not cut off from the whole of the central nervous system;* they remain connected with their lowest motor centres, motor centres ulterior of the lesion, by fibres extrinsic downwards of the level. This, in clinical language, although the lesion is of fibres in the morphological mass, the cord, is "cerebral paralysis" as certainly as the paralysis of hemiplegia from lesion of the internal capsule is (the same tract higher up but further fed by fibres from bulbar and pontal centres of the lowest level and by fibres from other lowest level centres in the aqueduct of Sylvius). In both cases the lesion is of fibres extrinsic upwards of the lowest level, of a set of fibres connecting two levels, lowest and middle.

I will illustrate more definitely the difference between the two kinds of paralysis, making once more the entirely arbitrary supposition, simply for ease of illustration, that but one segment, the fifth cervical, is crushed. Then, adopting Starr's conclusions,[5] the muscles of the arm "paralysed at the lesion" will be "deltoid biceps, coraco-brachialis, brachialis anticus, supinator longus, supinator brevis, rhomboid, teres minor, pectoralis (clavicular part) serratus magnus." These muscles are cut off from the influence of the whole of the central nervous system ("paralysis at the lesion"), except, of course, in so far as some of them are also supplied by segments above and below the fifth. Certain other muscles of the arms, those of the hands for instance, are also paralysed, but these muscles are not cut off from the influence of the whole of the central nervous system; they remain connected with their anterior horns. This motor paralysis of the hands is "paralysis below the lesion"; it is, like that of the legs, owing to destruction of fibres of the pyramidal tract.

The extreme seriousness of the cervical fracture dislocation case is not owing to destruction of the centres of the segments crushed—although this by itself is a great calamity, since there results from it the paralysis elliptically called "paralysis at the lesion"—but to severance of fibres which pass through the segments, is owing to "cutting connexions." I am not referring only to the severance of fibres of the pyramidal tract, fibres extrinsic upwards, which severance disconnects ulterior motor centres of the lowest level from motor centres of the middle level, and thus produces the paralysis elliptically called "paralysis below the lesion," nor only to the cutting across of sensory fibres, also fibres extrinsic upwards, disconnecting ulterior sensory centres for the legs from higher levels, cerebral and cerebellar, nor only to fibres extrinsic downwards from some citerior centres, gracile and cuneate nuclei, to the legs. These disconnexions entail a terrible calamity, but as regards life, the most serious thing is the severance of certain fibres, extrinsic and intrinsic of the level, by which severance the nervous mechanisms of the "four systems" are mutilated. I shall in the remainder of this note speak of the several abnormal conditions (I have fancifully called them "sub-maladies") which are consequent on mutilation of the nervous mechanisms of these systems.

I submit that the scheme of Lowest Level is especially useful in the analyses we are about to attempt. It is manifest that we cannot study the sub-maladies mentioned as merely resulting from a local injury of the cervical spinal cord; in their analysis we are concerned both with citerior and with ulterior centres of the lowest level. Were we to consider also a symptom from the sexual system (priapism), symptoms from the urinary system, and from the system of the hind-gut (defæcation) we should have to deal with nearly all the centres of the lowest level, citerior and ulterior. There is more to be said in this regard. We have spoken of the condition of the pupils and of the eyelids, consequent on lesion of those fibres which after their emergence from the cord pass by way of the cervical sympathetic to certain parts of the ocular musculature (fibres extrinsic downwards); this involves consideration of healthy citerior centres for the circular fibres of the iris, because the pupils contract more when the sympathetic fibres (inhibitory) are severed and do not dilate in a dim light when shaded. Theoretically there should be a "salivary symptom" in cervical fracture-dislocation cases; the sub-maxillary gland continues to be supplied by chorda fibres from citerior centres, but is bereft of sympathetic fibres. However, I know nothing of this imagined symptom in cervical dislocation-fracture cases.[6]

As I have mentioned, some cases of fracture-dislocation vary very much in their course; I have pointed out that the symptomatology will be traversed by super-venosity and also that, instead of orderly coöperation and amicable antagonism between the organs of the four systems, each organ is more or less "pursuing its private ends." Thus the separate consideration of the "sub-maladies" as if each were an independent and unvarying thing, is, of course, an arbitrary proceeding.

For the proper analysis of so complex a symptomatology, a vastly greater knowledge of physiology than I possess is required. What is to follow must be taken almost as remarks on mere symptoms. But just as one who wishes to be a good musical performer practises scales, so he who wishes to be a good diagnostician must study mere symptoms. If the symptomatology of the cervical fracture-dislocation case were thoroughly and correctly analysed a valuable

[3] If the speculation I advanced in THE LANCET of Feb. 23rd, 1895, on the difference between respiration proper (organic service of the thoracic cage) and so-called forced inspiration (animal service of the thoracic cage) were proved, there will be also cutting across of other fibres to the costal motor centres—fibres of the pyramidal tract from motor centres of the middle level (Rolandic cortex). These fibres are for "voluntary" movements of the intercostal muscles (for "voluntary expansion" of the thoracic cage, for the so-called forced inspiration).

[4] Motor fibres interconnecting lowest motor centres and the cerebellum have not been found; this is, of course, an objection to the hypothesis I hold as to cerebellar influence upon the anterior horns (lowest motor centres), as explaining, for example, the rigidity in hemiplegia and the tremor and rigidity of paralysis agitans.

[5] Starr's table is given in Osler's *Principles and Practice of Medicine*, second edition, p. 819 and seq. Osler makes the remark: "Movements, not muscles, are localised in the central nervous system, a point carefully to be borne in mind by the student." I have often insisted on this; yet in the text I speak of muscles for convenience.

[6] We should have a scheme of the lowest level so that in fracture-dislocation cases and in other cases we might be helped in our analyses of the complex symptomatologies produced. I have made such a scheme, but it is too poor a thing to publish.

Hosted by Google

contribution would be made to neurology. Were it right to suggest work for other people to do, I would commend the study of this complex neurological problem to well-trained physiologists.

Thermal System.—To begin with, I quote authorities on the great difference in the thermic state of different patients who have undergone cervical fracture-dislocation.

Hutchinson writes[7]: "The general result of my examination [of notes of fracture-dislocations of the spine] has led me to believe that, although increase of temperature is the rule, it is liable to not infrequent exceptions, and that some of these are very remarkable. Nor have I found it at all easy to explain why this should be so, *why, in fact, we should have some cases of fracture of the cervical spine in which the patient becomes very hot, and others in which he becomes very cold.*" (There are no italics in the original)

Weber[8] "has recorded cases where, after fracture of the cervical vertebræ (third, fourth, and fifth in one case, and third and fourth in the other) with severe lesions of the cervical cord, the temperature (in the axilla) reached 111° F. just before death, eight hours after the injury; while in the other case (taken in the rectum), immediately after death, and nineteen hours after the accident, it was 110°."[9]

So much for high temperatures; now for low temperatures. Jacobson[10] mentions a case recorded by Hutchinson[11] of a man aged twenty-eight years, who had fractured the fifth cervical vertebra, the cord being crushed at this level, with a temperature of 95·8° in the rectum, twenty-four hours after the accident; just before death, five days after the accident, it was 95° both in rectum and axilla. "It is expressly stated that the patient was not during the greater part of the time suffering in the least from shock, and that though the face was with the rest of his body almost as chilly to the hand as a corpse, yet his lips, ears, and face were florid twenty-hours after the accident, 'of a good rosy colour' on the third day, becoming blue only during the last twenty-four hours of life." Jacobson gives details[12] of a case recorded by Nieden[13]; "fracture-dislocation of the first dorsal vertebra with crushing of the cord on this level, where there was progressive lowering of the temperature and pulse during the eleven days which intervened between the injury and death of the patient Thus the temperature fell steadily from 98·6° on the third day to 80 6° at the time of death. In the same interval the pulse, which on the third day was 68, full and strong, became slower and less perceptible, falling to 30 before death."

I shall deal only with those cervical fracture-dislocation cases in which the temperature is very high. Of course this is a very arbitrary proceeding; it is one which shirks the difficulties presented by other cases in which, or at a stage of which, temperature is low or very low.

Donald MacAlister in his very valuable Gulstonian Lectures on the Nature of Fever,[14] re-published by Macmillan and Co., writes in the third lecture: "The thermal nervous system has three parts; let us call them briefly the thermotaxic or adjusting, the thermogenic or producing, and the thermolytic or discharging mechanism.[15] ..... In the ascending scale of evolution we seem to rise from the thermolytic to the thermogenic and thence to the thermotaxic nervous system." He regards fever "as a 'dissolution,' a progressive negative process" and recovery from fever as a process of re-evolution. His remarks on these matters are very interesting. In the cervical fracture-dislocation case the nervous mechanisms of all three parts of the thermal nervous system are damaged suddenly together; thus the "fever" produced, if I may call it a fever, will not have so orderly a course as fevers proper.

The muscles are the main parts concerned in thermogenesis; they, under the influence of the nervous system, unceasingly produce heat in entire and healthy men. I submit the hypothesis that in cervical fracture-dislocation cases, when the temperature is very high, as it is in many of these cases, the "muscles below the lesion," those connected with ulterior motor centres, produce much more than normal. Here, however, is a difficult question; the high temperature in cervical fractured-islocation cases may not signify increased thermogenesis, but only greater emission of heat. We cannot make calorimetrical researches on our patients to decide the question. We must bear in mind that from arterial relaxation, owing to severance of all fibres passing from the medulla vaso-motor centre (fibres extrinsic downwards) thermolysis will be greatly facilitated.

It must be borne in mind, as already urged, that there are in the cases under remark two very different kinds of paralysis. There is that "at the lesion" in which some few muscles of the arms are cut off from the influence of the whole of the central nervous system. No doubt these muscles cease, or soon cease, to produce heat. Although the amount of heat not produced consequent on these few muscles being bereft of influence from the central nervous system is a negligible quantity, the consideration of this kind of paralysis in comparison with the other kind in regard to the state of the thermal system of our patient is important for purposes of illustration. The other kind of paralysis, "paralysis below the lesion," is very different from that "at the lesion," the muscles concerned being in a very different case; the muscles in the "paralysis below the lesion" remain connected with their anterior horns (some lowest motor centres). These muscles never move (molar movement), but this is not, I submit, because their anterior horns are functionless, but because the higher levels can, on account of the transverse cervical lesion, no longer "get at" these lowest motor centres to put them into activity. But may not these uninjured ulterior motor centres, or some elements of them,[16] continue so to act on the muscles they supply as to cause them to produce heat? My speculation is that in the cases with a high temperature these centres over-act to that end, and cause the muscles to produce more heat than normal. (Once more I admit the inadequacy of this exposition of the state of the thermal system in cervical fracture-dislocation cases; cases with an abnormally low temperature not being taken into account.)

It is so important with regard to the thermal system, to distinguish the paralysis in which muscles are cut off from the whole of the central nervous system, from that paralysis in which they are not cut off from the whole of that system, but only from its higher levels, that at the risk of tedious iteration, I will consider the matter from another point of view. Suppose for mere illustration's sake, that it is possible (of course, it is not) to limit in the case of a dog the action of curara to the motor nerve endings of what we may call the same muscles as those which in the cervical dislocation-fracture case of man are "paralysed below the lesion"; these muscles in the curarised dog would, so long as the poisoning lasted, be cut off from the influence of the whole of the central nervous system and would produce no heat; the animal would be rendered "cold-blooded," except for the heat produced by other muscles, "muscles above the lesion," the motor nerve endings in which we are imagining to be spared from the action of curara, and by the liver and other parts of the body. And thus the muscles of which the motor nerve endings are poisoned would, to borrow a term and a notion from Hutchinson, become "refrigerators" to the rest of the body. But, I repeat, in the cervical fracture-dislocation case of man, "the muscles below the lesion" are in a very different case since they remain connected with their lowest motor centres, although these centres are, by severance of fibres of the pyramidal tract, disconnected from motor centres of the middle level (Rolandic cortex). Could we in the case of the dog curarise only the motor nerve endings to the same few muscles, as those which are supplied in the case of man by the crushed sub-phrenic cervical anterior horns, or, let us say, referring back to a former illustration, those muscles which are, according to Starr, supplied by the fifth segment, which we shall suppose is the only one crushed in man, there would be very little, next to no, diminution in the dog's production of heat, the amount of muscle cut off from the central nervous system being so small. But in this imaginary case of very localised action of curara in the dog, there is not a transverse lesion of the cervical cord at the level of the fifth segment as there is in the fracture-dislocation case of man.

I submit the hypothesis that the ulterior motor centres in cervical fracture-dislocation cases of man with a high

temperature continue functionable for thermogenesis, and that from section, by the infra-phrenic transverse lesion of the cord, of "inhibitory nerves" of the thermal system coming down from some centres of higher levels, or from some citerior centre of the lowest level (thermotaxic mechanism of MacAlister) to these ulterior motor centres, they, or some elements of them, so rise in activity that great increase of thermogenesis by the muscles they remain connected with occurs. The suggestion is that the very high temperature in some cervical fracture-dislocation cases does signify greater thermogenesis, although no doubt there is greater thermolysis too. Cases with a high temperature, in which death occurs in a few hours or days, have been so far dealt with. I shall now speak of the case of a man who lived many years after cervical fracture-dislocation.

There is repetition in the foregoing from a lecture entitled Neurological Fragments, which I published in THE LANCET of March 5th, 1892. I quote the following from that lecture: "A patient of the late Mr. Hilton lived fourteen years after a fracture-dislocation crushing the cervical cord across below the emergence of the phrenic nerves. Did not the 'muscles below the lesion' in this man produce heat when they were 'paralysed'? If they did not, they would have had to share the heat produced by the 'muscles above the lesion' (and of course by other parts of the body), and would thus be refrigerators." If in Hilton's patient[17] there was excessive thermogenesis soon after the accident, we must suppose that this greatly increased generation of heat continued for a short time only. It is not likely that the patient had a very high temperature for fourteen years, and it is not likely either that all the muscles "paralysed below the lesion" produced no, or very little, heat during that time. The patient was twenty-one years of age at the time of the accident. He was taken about on a four-wheeled cart by a boy.[18] "The patient used to amuse himself or earn his living by making copies of engravings with his mouth."[19] So far as I can judge by the report, this patient was by no means "cold-blooded" and made the best of a sadly maimed life. Consider also the case of B. G., a dorsal case, narrated in Note XVI., THE LANCET, Dec. 12th, 1896. She certainly was in no degree "cold-blooded"; her temperature was occasionally raised (102° F., once 103·5°), but never persistently raised; sometimes it was 97°; she was cheerful and occupied herself in needlework and reading.

I am dealing, I repeat, in this note with cervical fracture-dislocation cases in which death occurs in a few days. Probably when the patients live a very long time, as did Hilton's patient, or in chronic dorsal cases like that of B. G., the ulterior motor centres become a little more nearly normal in function; very possibly small vaso-motor centres in the ulterior part of the lowest level gain greater power and thus thermolysis will become more nearly normal. More generally it is probable that when a patient lives a long time the part of his lowest level below the transverse lesion of the supra-lumbar cord (ulterior part) recuperates to some little extent.[20] In the case of the girl B. G., the catamenia were normal; the return of her knee-jerks probably showed some recuperation of the anterior horns concerned; in her, however, the lowest level nervous mechanism for the bladder, which on her admission was so far effective that the bladder emptied itself at intervals, failed later. In her case, however, possibly the transverse lesion was not completely transverse. In Hilton's patient there were other phenomena showing functionability of some ulterior centres which I shall mention when speaking of the state of the Sexual System.

The Circulatory System.—There is cutting in two of fibres descending in the cord from the accelerator[21] (medulla) centre (fibres of the lowest level extrinsic downwards) and also of fibres from the great (medulla) vaso-motor centre (also fibres extrinsic downwards). (I have spoken of severance of the latter as facilitating thermolysis.) The pulse is infrequent and relaxed (low tension). We have here to bear in mind that the cardio-inhibitory centre of the lowest level is intact, and that the fibres (extrinsic downwards) from it by way of the vagi to the heart are so too; possibly when respiration becomes very inefficient the heart may beat still less frequently from stimulation of that centre by supervenous blood, and, perhaps by great heat also, until the time comes when the cardiac musculature itself succumbs to those agencies.

The difficulty is to explain how it happens that there is infrequent pulse in the cases remarked on. Landois and Stirling[22] write: "The accelerating centre is certainly not continually in a state of tonic excitement, as section of the accelerans nerve does not cause slowing of the action of the heart; the same is true of destruction of the medulla oblongata or of the cervical spinal cord. In the latter case, the splanchnic nerves must be divided beforehand, to avoid the slowing effect on the action of the heart produced by the great fall of blood pressure consequent upon destruction of the cord, otherwise we might be apt to ascribe the result to the action of the accelerating centre, when it is in reality due to the diminished blood-pressure" (Cyon).

The following is from Hutchinson's article *On Dislocations and Fractures of the Spine, London Hospital Reports*, vol. iii., 1866, pp. 365-6. I give this quotation partly because it contains remarks on a tract of hyperæsthesia which is sometimes a great addition to the patient's misery, and partly because the quotation deals in a striking way with the state of the circulatory system in some cases of cervical fracture-dislocation. Hutchinson writes:[23] "Unless the injuries be in the cervical region, no influence upon the heart's action is observed. When high up a very peculiar condition results. The pulsations are diminished in frequency and the pulse (from the paralysis of the artery) is remarkably full and large. Your first impression is that it is much slower than you find it to be on counting, at least, this has generally been my experience. It feels remarkably deliberate. The manner in which the heart seems exempted from all share in the patient's general excitement is sometimes very curious. I recollect well going to the bedside of a poor fellow who had been admitted a few hours before with a fracture of the fifth cervical. It was one of those cases in which the boundary tract of skin between that quite paralysed and that enjoying perfect sensation, was excessively tender. He was screaming with pain, and his countenance expressive of the utmost suffering and anxiety, yet his pulse, which we might have expected to be quick and excited, was slow, full and deliberate, about 48 in the minute. Although the pulse after injuries to the cervical cord becomes slow, it does not intermit."

Considering the complex situation of the circulatory system—severance of the accelerator fibres (which severance in a lower animal the physiologist tells us does not slow the heart), the severance of all fibres from the medulla vaso-motor centre, the intactness of the cardio-inhibitory centre and the possibility that this centre is over-stimulated when the blood has become very venous, and the possibility that minor vaso-motor centres below the transverse cervical lesion are also then stimulated—I refrain from attempting an explanation of the infrequent action of the heart in cases of cervical fracture-dislocation.

---

[17] Hilton recorded the case in his *Rest and Pain*." I quote from the second edition by Jacobson, p. 102 and seq. *The heading of the report of the case is*, "*Case of Injury to fifth, sixth, and seventh Cervical Vertebræ; Paralysis and Loss of Sensation in the Upper and Lower Extremities: the patient lived fourteen years, and then died from another accident.*"

[18] As to the cause of his death: "He was upset, and, as he could not put out his hands to save himself, he fell with great violence upon the ground; this led to some chest affection which occasioned his death in a few days."—Hilton, op. cit., p. 105.

[19] Hilton, op. cit., p. 104.]

[20] In a lower mammal there will presumably be after a transverse supra-lumbar lesion considerably more recuperation of the ulterior part of the cord than in the case of man. I take the following from Landois and Stirling's Physiology, Fourth Edition, vol. ii., p. 786. I suppose the intercalation marked by square brackets in the original is by Stirling. "In mammals (dogs) the following reflex acts are performed by the posterior part of the spinal cord, even after it is separated from the rest of the cord: [In mammals, however, the cord takes a long time to recover from the shock of the operation compared with the time required for this result in cold-blooded animals.] Scratching with the hind feet a part of the skin which has been tickled (just as in intact animals); the movements necessary for emptying the bladder and for defecation, as well as those necessary for erection; the movements necessary for parturition (*Goltz, Freusbery, and Gergens*). Coördinated movements do not as a rule occur simultaneously in portions of the spinal cord lying widely apart after removal of the medulla oblongata. According to Ludwig and Owsjannikow, the medulla oblongata perhaps contains a reflex organ of a higher order which forms, as it were, a centre for combining through the medium of the nerve fibres the various reflex provinces in the spinal cord." I should suppose this centre in the medulla to be the coördinating centre of the whole of the lowest level—the "highest centre" of the lowest level.

[21] In the dog the accelerator fibres "leave the spinal ford as medullated fibres by the anterior roots of the second and third dorsal nerves, and it may be by the fourth and fifth nerves as well." Landois and Stirling, Physiology, fourth edition vol. ii., p. 827. Although I use the term "accelerator *centre*," Landois and Stirling only say, "It is more than probable that a centre exists in the medulla oblongata which sends accelerating fibres to the heart."

[23] *Effects of Injuries to the Cord upon the Heart*

Hosted by Google

The Respiratory Nervous System.—There is cutting off of the costal motor centres from the Respiratory centre, a Superior centre in the bulbar region of the level, by severance of intrinsic fibres of the level; the laryngeal and phrenic motor centres remain in connexion with that Superior (respiratory) centre by intrinsic fibres. As venosity increases the respiratory centre being strongly stimulated by super-venous blood, and perhaps by great heat too, the diaphragm will act more and thus for a time there will be some compensation for the effects on respiration of suddenly occurring paralysis of the intercostal muscles.

Paralysis of the intercostal muscles alone or of the diaphragm alone does not seem to greatly trouble a man who is, for other reasons, obliged to lie quiet in bed; there seems to be no reason why in those circumstances he should not live for years, in spite of either paralysis. But in the cervical fracture-dislocation case the paralysis of the intercostals is suddenly produced, a very important thing. Besides, as we have seen, there is mutilation of the nervous mechanisms of the three other systems; there is much more than paralysis of the chest-walls to cause death. I say this because whilst the abnormal state of the respiratory system properly attracts great attention, not enough attention is given to the abnormal state of the other three systems.[24]

The Digestive System.—In some cervical fracture-dislocation cases there is great distension of the intestines and constipation; I speak of the distension only, although the interpretation of the constipation is similar. In the analysis of this sub-malady we require to take into very particular account certain citerior and certain ulterior centres of the lowest level, both of which are uninjured. The intestines (I here exclude the hind-gut[25] from consideration) have two direct sources of innervation from centres of the lowest level; there is one, motor, from a centre of the medulla region of the level, by way of the vagi, and there is another, inhibitory, by way of the splanchnic nerves, from centres of the dorsal region of the level (in the dog by way of the sixth and some lower dorsal roots, perhaps from the intermedio-lateral tract, which Mott thinks gives off visceral fibres). I suggest that the centre in the medulla region of the level is not only motor, but that it has also a certain inhibitory function of which I go on to speak. In an entire man I suppose that the two sets of centres of the level, medulla and dorsal, being connected by intra-central fibres, are in a relation of amicable antagonism, and that the centre of the medulla region of the level can not only act motorily upon the intestines by way of the vagi, but that, by the intra-central fibres suggested, it continuously slightly inhibits the "dorsal centres" which by way of the splanchnic nerves are inhibitory of intestinal movements; there is inhibition of inhibitory centres. When in an entire man the medulla centre comes into activity for defæcation, or rather for intestinal action preparatory to that of the hind-gut, two things, according to the speculation advanced occur; there is direct motor action of the medulla centre upon the intestines by way of the vagi, and there is also by that medulla centre so much greater inhibition than what I have spoken of as slight and continuous, of the inhibitory dorsal centres that they cease altogether to inhibit the intestines and thus the gut is *surrendered to* the direct vagal motor influence. In other words, there results from action of the medulla centre a direct "making go" of the intestines and indirectly a "letting go" of them. So much for the entire man; next for the man whose central nervous system has been cut in two at the point mentioned (infra-phrenic cervical cord).

In the cervical fracture-dislocation case there is a complete transverse lesion of the cord between what I now call the citerior centre for the intestines and the ulterior centres for them; and certainly in many cases great distension of the abdomen does occur, often to such an extent as to be a very serious addition to the patient's misery.[26] How does this distension result from the infra-phrenic cervical transverse lesion of the cord—from a *negative* lesion of that part? It does not result directly from that lesion. My speculation is that the negative transverse lesion divorces the medulla centre from the dorsal centres by cutting across fibres (intrinsic elements of the level) which connect the two—fibres from the centre of the medulla region of the level by which in an entire man that medulla centre slightly inhibits continuously, and occasionally inhibits strongly, the dorsal inhibitory centres. In the fracture-dislocation case the citerior centre has become in effect motor only; that is to say, the inhibitory part of it can no longer act on the ulterior dorsal centres to compel them to cease to inhibit the intestines; thus the intestines are not surrendered to the action of the motor part of the citerior centre. Indeed, the ulterior centres in question, being no longer inhibited, rise in inhibitory power upon the intestines and keep them dilated, so that motor action upon them by the vagal fibres from the citerior (medulla) centre is ineffective. This is making the assumption that the (dorsal) ulterior inhibitory centres when themselves no longer inhibited can overpower by their enhanced inhibitory influence the motor action upon the intestines of the (medulla) citerior centre.[27]

I neglected in the foregoing remarks on the digestive system the complications induced by great venosity, which may become great in the cases under remark. It is said that stimulation of the splanchnic nerves causes peristalsis when the circulation of the blood in the capillaries of the intestines has become venous.

The Sexual System.—There is, I believe, a dislike to the supposition of a hierarchy of inhibitory centres, but the case of cervical fracture-dislocation supplies us with one symptom, priapism,[28] which I submit is difficult of interpretation on any other supposition than that of removal of inhibition from a centre which is itself inhibitory. In priapism there is dilatation of the arteries of the penis; during erection of the penis in entire men its arteries are inhibited (Eckhardt) by over-activity of a

---

[24] I believe that paralysis of the intercostal muscles is often overlooked in patients who are bedridden or who lead a very sluggish life indoors; indeed, it has to be looked for as the patient when obliged to lie quiet in bed may suffer very little indeed from it and may exhibit no signs of venosity. I have seen it in a case of disseminated sclerosis. Some years ago my then house physician at the London Hospital, Dr. Howard Sturge, told me that a woman's breathing became abdominal when she was under chloroform, a great change from the normal manner of respiration of her sex. I have seen this abdominal mode of breathing in surgical anæsthesia several times since, as I have mentioned (No. XV., THE LANCET, Feb. 23rd, 1895, Footnote 6), both in men and women; there being paralysis of the intercostals, the chest sinking in inspiration. I am not speaking generally of "defective respiration" but of the breathing being solely diaphragmatic, consequent on paralysis of the intercostal muscles. Sometimes in men the respiration under chloroform is almost solely costal. Much will, I suppose, depend on the stage of anæsthesia. I learn from Dr. Hewett's very interesting work, *Anæsthetics and their Administration*, p. 219, that "Snow stated that thoracic movements usually cease before abdominal." We must remember that the diaphragm alone can raise and evert the lowest ribs so that their movement is no proof that some of the intercostals escape when the higher intercostals do not act. The respiration may become solely abdominal in coma, even in women, from other causes than chloroformisation or etherisation.

[25] The hind-gut is under different nervous government. In this note I omit consideration of a symptom, incontinence of fæces, referable to this part of the intestinal tube. (See Hutchinson, London Hospital Reports, vol. iii., 1866, pp. 366-7.) Nor shall I speak of the vesical apparatus (I again refer to Hutchinson, op. cit., pp. 367-8). What he then wrote was written before the days of antiseptic surgery.

[26] Properly there is inaction of the circular fibres of the intestines from strong inhibition of them, so that gases accumulate.

[27] It has long been a custom with some prescribers to add a little belladonna to aperient pills. I suppose this drug facilitates peristalsis by reducing the potency of the inhibitory fibres of the splanchnic nerves, and possibly also by stimulating the vagus centre, or, it may be better to say by stimulating the centre in the medulla from which come the motor fibres which pass by way of the vagi to the circular muscular coat of the intestines. It occurred to me that this drug should be useful in the "distension" spoken of in the text; by partially paralysing the inhibitory fibres of the splanchnics, the vagal fibres would then be less opposed in their action on the circular muscular coat of the intestines. I saw a patient with Mr. Wreford who had essentially the symptomatology of a cervical fracture-dislocation case but from disease; the patient's abdominal distension was much reduced when he was taking belladona which I advised for the theoretical reasons mentioned, Dr. James Taylor saw this patient with us and agreed that improvement attended the use of the drug.

[28] There is not, or there is not commonly, more than turgescence of the part (when the catheter is passed the organ becomes more turgid). If the muscles which on contraction impede exit of blood from the penis are paralysed, we could not expect there to be such priapism as occurs in normal erection or in the so-called idiopathic priapism of surgeons. But the ulterior centres of the lowest level for the muscles in question are intact, and although they are cut off from higher levels these centres, perhaps, sometimes come into action and produce muscular contraction. In a case (*Fracture-Dislocation between the Fifth and Sixth Cervical Vertebræ.—Complete Paralysis of all Nerves below the Fifth Cervical.—Death*) recorded by Thorburn (Surgery of the Spinal Cord," p 8), "The penis was subject to frequent erections with seminal emissions." This patient died twenty-one days after the accident. We rarely see—I never saw—a case of cervical fracture-dislocation in which the cervical cord is crushed completely across in which the patient lived for years. But such a case, mentioned earlier in the text, when speaking of the thermal system, is recorded by Hilton ("Rest and Pain," second edition, by Jacobson, p. 102 *et seq.*); the patient lived fourteen years. Priapism and seminal emissions occasionally occurred. Hilton wrote, p. 104, *op. cit.* (from notes taken "during the latter period of the patient's life"). "erections of penis are frequent, and last a quarter of an hour, with slight escape of seminal fluid occasionally." (Priapism occurs in cases of transverse lesions of the cord lower than its cervical region.)

Hosted by Google

centre in the sacral part of the cord (as I should say in the sacral region of the lowest level) giving off the nervi erigentes. But in entire men there is, neglecting obvious occasional exceptions, flaccidity of the organ, and thus I assume that the sacral centre mentioned is in them continuously kept down (inhibited), either by a medulla centre of the level (and if so, by intermediation of fibres intrinsic of the level) or by a centre of some higher level (and if so, by intermediation of fibres extrinsic upwards of the level). After the occurrence of the transverse lesion of the cord in cervical fracture-dislocations priapism occurs, and it lasts for a time after the accident. Now this state of the penis is consecutive to a *negative* lesion anatomical miles above the now over-acting sacral centre. Surely there is here something "taken off" that sacral centre—no longer inhibition of a centre itself inhibitory. (It is important to note that priapism may be present during "shock" in cervical fracture-dislocation cases (Hutchinson).) Here is another illustration of the principal spoken of at the beginning of Note XVI.[29] Here again is a problem in physiology. The sacral centre is untouched by any pathological process or injury; that centre is simply "let go."

I submit that the hypothesis of intra-central inhibition applies more widely in the lowest level than as illustrated by the two symptoms of the fracture-dislocation case, distension of the abdomen (digestive system) and priapism (sexual system). That the cardio-inhibitory centre reins in the heart by the vagi is accepted doctrine, but I submit the speculation that this centre also continuously inhibits the accelerator centre. On this hypothesis, increased activity of the cardio-inhibitory centre in an entire man makes the heart beat less frequently by two modes of action: by direct action on the heart by way of the vagi and by greater inhibition of the accelerator centre. I will illustrate this hypothesis by applying it to the interpretation of a well-known nervous malady. In Graves's malady the great frequency of the pulse, to limit attention to that symptom, has been (Sattler) ascribed to lesion of the cardio-inhibitory centre. Adopting the speculation that there is a negative state of, or of much of, this centre, I submit that the heart beats more frequently, not only because it is less inhibited by way of the vagi, but also because the accelerator centre, not being inhibited, or being less inhibited than normally, the cardio-inhibitory centre is "let go" to act more on the heart. On the supposition made, the increased frequency of the pulse in Graves's malady is of two-fold origination from one negative lesion.

It may be said, of cases of Graves's malady in which the pulse is not very frequent, that loss of inhibition on the heart alone is enough to account for the greater rate. Sir William Broadbent writes,[30] speaking of Graves's malady: "The pulse is seldom under 100 per minute, often 120 or over, sometimes 160 to 200. In a case recently under observation the pulse was never under 160 for many weeks, and in paroxysms of palpitation it sometimes numbered 240 for several days, reaching at times 300." Would the higher rates[31] Broadbent mentions be owing to cessation of inhibition on the heart alone? Broadbent, in continuation of the observations quoted, writes: "The beat is sudden, sharp, and vehement; and its very frequency renders it short. The artery has not time to subside, but, though it is full between the beats, there is no peripheral resistance and no real pulse-tension."

The accelerator centre in healthy people is not, according to physiologists, in continued activity; the sacral centre in healthy people is not, so far, at any rate, as the arteries of the penis are concerned. We might infer this from the flaccidity of the penis, except on particular occasions; it is said that section of the nervi erigentes makes no change in the state of the organ, although excitation of the peripheral ends of these nerves produces turgescence of it. And although the pulse is infrequent in many cases of cervical fracture-dislocations the physiologist tells us that section of the accelerans nerve does not slow the heart (see quotation from Landois and Stirling in a footnote to an earlier part of this Note) and yet excitation of its peripheral end makes the heart beat more frequently. It may be that in healthy men the accelerator motor centre only comes into increased activity on the diminution of inhibition of it, just as, to illustrate by an abnormal state, in the fracture-dislocation case the arteries of the penis are dilated and the organ thereby made turgid only on the taking off of inhibition from the sacral inhibitory centre, which gives origin to the nervi erigentes.[32]

I will now remark on the indefinite meaning of the word paralysis in some of its applications. In the cervical fracture-dislocation case the "paralysis at the lesion" is "spinal," the "paralysis below the lesion" is mainly "cerebral"; the two paralyses are (vide *supra*) of very different kinds. And in reference to the illustration from the effects of mutilation of the nervous mechanism of the digestive system, it is from a scientific standpoint erroneous to say "the intestines are paralysed"; they are inactive, but the medulla centre can still act upon them by the vagi although it effects nothing, and for the rest of the condition they are kept dilated by abnormally high inhibition; there is simply cutting of connexions between two centres for the intestines, the centres themselves being intact. It is for this reason that I have sometimes used the term "field of a symptom." We cannot, to take another illustration, say that the iris is paralysed in the cervical fracture-dislocation case; the pupil contracts to light and during accommodation, but fails to dilate in a dim light when shaded (Hutchinson); the iris is "the field of a symptom." The heart is one of the parts of the body which has "double different innervation"; it is in the fracture-dislocation case cut off from the accelerator centre, but remains connected with the vagus centre. To say that it is, or rather that it is partially, paralysed, is misleading, especially considering retention of its inherent power of acting.

I have to thank my friend, Dr. Rose Bradford, for looking over the foregoing.

[29] THE LANCET, Dec. 12th, 1896.

[30] The Pulse, p. 89.

[31] Lauder Brunton, Pharmacology, Therapeutics, and Materia Medica, Third Edition, p. 288, writes: "In man the effect of the vagus on the heart is intermediate between that of the rabbit and dog; so that if the normal pulse is between 70 and 80 in the minute, it rises to between 140 and 180 when the vagus is paralysed by atropine (Van Bezold)."

[32] It occurred to me that if the hypothesis of intra-central inhibition, as thus applied in the case of the heart, were valid, excitation of the central end of the superior laryngeal nerve might make the heart beat less frequently by acting on, and increasing the power of, the cardio-inhibitory centre *when the vagi are divided*; for according to that hypothesis increased action of the cardio-inhibitory centre would inhibit (or inhibit more than normally) the accelerator centre. Some experiments on dogs which Dr. Risien Russell made for me show that there is no such result from that excitation in those circumstances.

A NOTE ON THE OCCURRENCE OF METRORRHAGIA AFTER THE MENOPAUSE IN CASES OF OVARIAN TUMOUR.

BY ARTHUR H. N. LEWERS, M.D. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

DURING the years of menstrual life—that is to say, from the age of puberty, which may be taken as about fifteen years, up to the menopause, which is normally established between the age of forty-five and fifty years—the influence on menstruation exerted by the development of an ovarian tumour is well known. In about one-third of all such cases menstruation is unaffected; as regards the remainder, in the majority there is a tendency in the direction of amenorrhœa, the periods occurring either less frequently or the quantity lost each time becoming diminished, or both these conditions may be combined. In a minority of cases the development of an ovarian tumour is marked by the occurrence of menorrhagia. When, however, we come to inquire about cases where an ovarian tumour commences to develop *after* the menopause, as to whether hæmorrhagic discharges from the uterus may be caused by the ovarian tumour and be rightly regarded as symptomatic of it, we find little or no information on the point in the majority of books to which reference would most naturally be made. Thus, for instance, in the works on the "Diseases of Women" by Barnes, Thomas, Hart and Barbour, and Skene there appears to be no notice of the point, and the same applies to several other works. In West and Duncan's "Lectures on the Diseases of Women" there is an analysis of ninety-four cases of ovarian tumour with reference to the way in which menstruation was affected. It is merely stated there that "in seven

Hosted by Google

cases menstruation had ceased before the disease began." Similarly in the "System of Gynæcology" by Allbutt and Playfair recently published there is an analysis of 118 cases as regards this point, and it is mentioned that twenty were cases before puberty or after the menopause, apparently implying that no menstruation or pseudo-menstruation was to be expected as the result of the growth of the tumour in cases of this kind. It may fairly be concluded that the occurrence of bleeding from the uterus after the menopause in cases of ovarian tumour is a somewhat rare event. That this symptom may occur is, however, mentioned by Pozzi in the following passage: "After the menopause congestive phenomena have been noted in the uterus leading to the re-appearance of a more or less irregular bloody discharge, which makes the patient believe menstruation has returned." At this passage there is a reference to a paper by Terrier in the *Revue de Chirurgie*, 1884, p. 1, but on looking up this paper it appears that he is speaking of the appearance of bleeding subsequent to the operation for removing the tumour, which is quite a different thing. The passage by Terrier is as follows: "To resume, in women already aged, accustomed, so to speak, to the menstrual flow, the periods have a certain tendency to re-appear after the removal of both ovaries. But this red discharge only lasts a few months, and is not slow to disappear altogether."[1] In Garrigues' "Diseases of Women," 1894, p. 565, the point in question is clearly but very briefly mentioned. He says: "On the other hand, even after the menopause, new hæmorrhagic discharges from the uterus may occur."

A special importance attaches to the causes of bleeding after the menopause, since in such a large proportion of cases, as is well known, this symptom is due to the presence of a malignant growth at some part of the genital tract. It is interesting, therefore, to keep in mind that this symptom may in rare cases be due to the fact that an ovarian tumour is in process of development. While the tumour is still small, especially in a very stout patient, the occurrence of bleeding after the menopause may not improbably excite a suspicion of cancer. Without doubt in all such cases the possibility of the presence of cancer should always be thought of first, but when cancer has been excluded by careful and repeated examination—and in some cases this is only possible after dilatation of the cervix—it is satisfactory to bear in mind that there are causes for metrorrhagia after the menopause other than cancer, and that the development of an ovarian tumour is in rare instances one of them. The following case is an example of it.

A woman aged fifty-four years was admitted into the London Hospital under my care on Jan. 6th, 1896. She was a widow and had had seven children. She was sent to me by Mr. W. H. Piercy Fox. She had first noticed a swelling in the abdomen about six months previously, but she thought that it might have been present longer without her noticing it, as she was very stout. The swelling in the abdomen had increased very rapidly, she thought, during the last six weeks, so that, in her opinion, the abdomen was now twice the size it was three months before. For the last three months she had suffered very much from dragging pains and general discomfort in the abdomen with dyspnœa. She was only fairly comfortable when lying on her right side. About three years previously the catamenia ceased, and she "saw nothing" for two years. There was then a period of bleeding, some blood coming away daily for six months. Then there was an interval of three months without bleeding. During the last month there had been a continuous red discharge daily. Up to three years previously she had been regular. She had "suffered from her chest and heart" for some years, with a good deal of shortness of breath. On examination the physical signs were those of an ovarian tumour reaching six and a half inches above the umbilicus. The circumference of the abdomen was forty-five inches at the umbilicus. On vaginal examination some brown discharge was seen about the external genitals, and the speculum showed some sanious discharge in the external os, but the cervix appeared normal. The sound passed three inches. Tilting the uterus with the finger gave one the impression that it did not form part of the large tumour in the abdomen.

On Jan. 23rd the patient was anæsthetised with the A.C.E. mixture and the abdomen opened by the usual incision. On opening the peritoneum a good deal of fr e fluid was seen; this was soapy and of thick consistence, and at once suggested that the cyst had burst, as was found to be the case. Most of the loculi of the tumour were small, and the size of the tumour could not be materially reduced by punctuting with the trocar. The incision was therefore extended above the umbilicus, and the tumour removed practically entire. An interesting point was the presence of recent adhesive peritonitis generally over the intestines and, in fact, over whatever part of the peritoneal surface came into view. The patient had had no acute symptoms before the operation, no rise of temperature, acceleration of pulse, vomiting, or more pain than the mere distension of the abdomen would sufficiently account for, and she walked to the operation table. Yet the cyst had burst and the extravasated contents had set up the general adhesive inflammation of the peritoneum above described. I had a similar case about five years ago, where, in spite of the rupture, there were no symptoms. In the present case the peritoneum was irrigated with warm saline fluid, and, a Keith's tube having been inserted, the rest of the wound was closed in the usual way. The tube was removed on the third day, and the patient made an uninterrupted recovery.

Apart from the bursting of the cyst before operation, an interesting point in the case is the return of a sanguineous vaginal discharge after complete cessation of the catamenia for two years. Generally of course after so long a period of amenorrhœa the re-appearance of blood suggests malignant disease of the uterus; but so far as could be ascertained, without dilating the cervix, the uterus in this case was perfectly healthy. It seems certain that the metrorrhagia was to be accounted for by the development of the ovarian tumour exciting a sympathetic congestion of the uterine mucous membrane. I have seen the patient several times during the past year, and since leaving the hospital she has never had any return of the sanguineous discharge, and she remains quite well.

Harley-street, W.

CASES OF STREPTOCOCCUS INFECTION.[1]

BY G. LENTHAL CHEATLE, F.R.C.S. ENG.,
ASSISTANT SURGEON, WEST LONDON HOSPITAL, AND KING'S COLLEGE HOSPITAL.

WHERE it is practicable my endeavour is to make an efficient bacteriological examination of every case that possesses evidence of a bacterial nature. The result of an investigation of this kind sometimes actually makes the diagnosis and at other times leads to its confirmation. Consequently, it has a marked influence upon the prognosis and treatment even in the course of ordinary clinical surgery. There can be no doubt that it is an addition to the task of ordinary hospital work, but as experience increases the burden decreases and this collection of evidence becomes part of the ordinary routine work. In cases that are to be treated by antitoxins or in those that are to be published concerning their use or otherwise this examination is a *sine quâ non*.

The histories of the following patients are selected out of a series of cases and they may prove of interest at the present time. In each of the six cases that are reported a virulent streptococcus pyogenes was found. Three of these were treated by the antistreptococcic serum as well as by operative and antiseptic surgical methods. One case was treated by the anti-streptiococcic serum alone. And two were treated by operative and antiseptic surgical procedures alone, which prove that properly conducted surgical means can cure even when the patient suffers from a severe streptococcus infection, whether that infection is pure or mixed. Therefore when a case is treated surgically as well as by the injection of the antitoxin it must not be too hastily assumed that the latter was the cause of the cure.

When reporting such cases as these it seems to me very important to state whether the infection was pure or whether it was mixed, for those cases in which there is a mixture of infection it is not always easy to definitely say which of the infecting organisms is the cause of most or of all the local and constitutional signs. For instance, a streptococcus infection may become super-infected by a highly virulent

[1] The antistreptococcic serum employed in the cases that were injected came from the British Institute of Preventive Medicine.

Hosted by Google

staphylococcus and under these circumstances the latter may be, for all we know, the chief cause of the local and constitutional signs. In fact it may become the predominant organism of the mixed infection. There are additional reasons for the separation, one is that the contaminating organism, or organisms, may modify the whole biological conditions, under the influence of which the streptococcus pyogenes exists and operates; and another is that a mixture of infection tends to lower the natural antiseptic properties of the part by further diminishing its physiological resistance. Hence it is not fair to publish the failure of an antitoxin to cure without stating the exact circumstances in which its curative power was tested. Therefore these cases have been divided into those of pure infections and those of mixed infections, and three of each are described in that order.

CASE 1.—A farrier, aged forty-five years, was admitted to the West London Hospital on Feb. 26th, 1896, under the care of Dr. Donald Hood. The patient's family and previous histories contained no positive evidence of importance. The patient had never suffered from gonorrhœa or syphilis, nor had he indulged in alcoholic excesses. On Feb. 22nd, five days before admission, the patient became suddenly ill and complained of severe prostration and one or two severe attacks of shivering. On the same day he complained of pain and noticed redness over the region of the right shoulder. During the next few days he suffered from more attacks of shivering and the right shoulder was blistered. Upon admission the patient was restless and excitable and his manner generally exhibited the premonitory symptoms of delirium tremens. His temperature was 104° F. The pulse was 160 and the urine was clear and free from albumin and sugar and remained so during the course of the illness. During the last few days there was a trace of albumin; streptococci were then sought for, but none were discovered, the urine being sterile. The condition of the skin over the region of the right shoulder was red, slightly swollen, and œdematous; the blister had healed. On March 1st the skin in the following situations was red, somewhat swollen, and œdematous: over the triceps of the left arm and the back of the left shoulder and over the ham muscles of the right thigh, as well as the previously described condition of the right shoulder. The morning temperature was 101° and 105° in the evening. On the 2nd the temperature was 101° in the morning and 105° in the evening. On the 3rd the morning temperature was 101° and the evening temperature 102°. On the 4th another and a similar patch appeared upon the skin over the region of the ham muscles of the left thigh. The tongue was now dry, brown, and transversely fissured. The temperature in the morning was 101° and in the evening before operation 102°. Dr. Donald Hood kindly asked me to see the case and gave it to me to keep under my care. The mental condition was the same and appeared to me to correspond with a similar state in cases similarly infected; fluctuation was demonstrated in the patches of the right shoulder and right and left thigh; there was no joint affection, whilst the local signs of the other regions had subsided almost to disappearance. The patient's work suggested glanders and the diagnosis lay between that and a streptococcus infection, the possible seats of infection being small superficial wounds upon the hands, wrists and forearms, caused by the dropping thereupon of hot cinders that had been blown into the air by bellows whilst he was at work. The patient was isolated until my subsequent bacteriological examination had been made proving it to be a case of streptococcus infection. The same evening the patient was anæsthetised, and after the parts were thoroughly purified incisions were made into the fluctuating areas described above; pus was found collecting in the subcutaneous tissue, but in the right thigh it was extending into and between the muscles. The pus was received into a sterilised tube; cover-glass preparations were made of it, and with it were inoculated tubes of agar, gelatin, bouillon, and potato. The cover-glass preparations were stained after the operation by Gram's method and Löffler's blue. Diplococci and streptococci were demonstrated in short and long chains. A rabbit and a male guinea-pig were inoculated with the pus; the rabbit died in less than twenty-four hours. Diplococci and streptococci were stained in the blood of its liver, heart, and peritoneal fluid. The guinea-pig after being ill recovered. Upon March 8th the media tubes, including the potato, showed a white growth. The gelatin was not liquefied. Streptococci were present and stroke cultures only led to the same result. The streptococcus chains in the fluid medium became much longer and more prolific than in the other tubes. The case was henceforward regarded as a pure infection of streptococcus. The operation of March 4th brought down the temperature, the wounds all did well, there was little or no serous discharge, and no pus or any further indications of inflammation. On March 5th the morning temperature was 99°, that of the evening being 101°. On the 6th the temperature was 98° in the morning and in the evening 100°. On the 7th, 8th, and 9th it was about 99° in the morning and 101° at night. On the 10th, 11th, and 12th the morning temperature was 99° and the evening 103°. During this time the general conditions had improved a little, but none of the areas unoperated upon had completely disappeared. The mental excitability still persisted. As no valuable progress had been made it was decided to inject the anti-streptococcic serum, so in the evening of the 12th 10 c.c. of the serum were injected. On the 13th the morning temperature was 101° and the evening temperature 103°. The patch previously noticed over the left shoulder on this day gave fluctuation; there was no redness. Pus was removed and stained and showed the same organisms as before. In the evening 15 c.c. of serum were injected. On the 14th the temperature in the morning fell, as usual, to 100° and remained there during the day. The patch previously noticed over the biceps of the left arm showed signs of fluctuation; there was no redness. Pus was removed and stained with the same result. After the operation 15 c.c. of serum were injected again. On the 15th, at 2 A.M., the temperature was 103°, at 12 A.M. 98°, and at 8 P.M. 103·6°. In the evening 15 c.c. of serum were injected. On the 16th, at 2 A.M., the temperature was 97°; in the evening 103°. In the evening 10 c.c. of serum were injected. On the 17th the temperature during most of the day was 101°. In the evening 8 c.c. of serum were injected. On the 18th, the serum having had no marked effect upon the patient's temperature or general condition, it was decided to increase the dose and inject it before the evening rise; therefore 35 c.c. were administered at 2 P.M., but at 8 o'clock the temperature was 104°. On the 19th the skin in front of the shoulder and below the clavicle and over the axilla of the right side was noticed to be œdematous and swollen; no fluctuation could be detected, but pus was liberated in a small quantity from the axilla; none could be found below the clavicle. The temperature, which before operation was 103·6°, fell after the anæsthetic and operation to 101°. The morning temperature was 100°. After the operation 30 c.c. of serum were injected. On the 20th the patient's general condition was much worse; in fact, the temperature from this date to the evening of the 24th varied between 103° in the morning and 105° in the evening. Upon the morning of the 26th he quietly died, and before death his temperature was 106°. The amount of serum injected had been 138 c.c. in the six days. The serum used was perfectly clear and sterile and there was never any local sign after its injection. The case was one of general infection, and this dosage of serum did not appear to have had any effect.

Necropsy.—Dr. Turner kindly allowed me to make the post-mortem examination with a view to the bacteriological part of the investigation. The blood from the heart, liver, spleen, and kidneys was subjected to the same tests as was the pus of March 4th and with practically the same result in the case of the blood from the liver and heart, but nothing could be grown upon the media or stained upon the cover-glass preparation of the blood from the spleen and kidneys. The viscera were normal and the microscopical examination of tissues hardened in methylated spirit showed no signs of lardaceous disease. At the top of, and in communication with, the wound of the right thigh there was a pocket of pus that was not detected during life, but it could hardly have been an important factor in the fatal issue of the case.

CASE 2.—A married woman aged thirty years was admitted into the West London Hospital on June 18th, 1896. Upon admission her temperature was 100° F. There were pain, redness, and swelling of the back and front of the right hand and forearm. Pus was just escaping from a small opening over the head of the metacarpal bone of the thumb. This wound was the seat of infection and was made by a splinter of wood whilst scrubbing the floor. Dr. Pardoe, who was house surgeon at the time, enlarged this opening, dressed it with cyanide gauze, and placed the limb upon a splint. On the following day (the 19th) the pain and swelling of the forearm were about the same. The temperature was 102°. On the 20th the temperature in the morning was 100° and at night

Hosted by Google

102°. On the 21st the morning temperature was 102° and that at night 104°. Dr. Pardoe asked me to see the case. The patient was evidently very ill and the whole forearm and hand was red and very swollen and œdematous. The tongue was dry and brown, and as it was quite late that night I made cover-glass preparations, stained them, and reserved the necessary operation till the next day. Diplococci and streptococci in short and long chains were again the only organisms stainable by Gram's and Löffler's blue. On the 22nd the patient was about the same, the temperature being 104°. Under an anæsthetic pus was found in front burrowing up the sheath of each finger and that of the thumb and also deep down on the surfaces of the metacarpal bones; also in the forearm pus was burrowing between the skin and superficial muscles, between the superficial and deep muscles, and between the deep muscles and the interosseous membrane as far up as the elbow. Free incisions were made into these areas as well as into the back of the hand and forearm. Over forty incisions were made, varying from one to four inches in length. Two of the biggest drainage-tubes obtainable (three-quarters of an inch in diameter) were inserted into the forearm, one between the superficial and deep muscles and the other between the deep muscles and the interosseous membrane. The limb was dressed as before and placed upon a splint. Before sending her back to the ward 30 c.c. of the anti-streptococcic serum were injected. Her temperature in the evening was 100°. On the 23rd the morning temperature was 99°, and 35 c.c. of serum were injected. The limb looked well and healthy; the skin showed fine longitudinal lines indicating the subsidence of the attack. The temperature remained down until June 27th, when it suddenly rose to 104°, but with no further treatment it came down as quickly as it rose and the patient made an uninterrupted recovery. Passive movement was begun early, and the last time she was seen, Nov. 28rd, 1896, she had very nearly regained perfect movement of her finger, wrist, and thumb. Supination and pronation were normal.

The pus removed from the limb upon June 22nd was subjected to the same test as in the first case; the rabbit died in twenty-four hours with diplococci and streptococci in the blood of the liver and heart and in the fluid of the peritoneal cavity. This case was one of localised streptococcus infection and was subjected to very extensive operative treatment as well as the injection of 65 c.c. of the antitoxin. From the surface of the wounds streptococci were stained during the whole of the healing period whilst the patient was in hospital. The seat of injection gave no sign of local complications.

CASE 3.—A child aged twelve months was admitted into the West London Hospital on Feb. 6th, 1896. The family history and the patient's previous history were practically of no importance. The mother stated that for six weeks the child had been ailing, and for the last three weeks had apparently pain in the back and legs that was more marked upon the child being washed or moved. The pain was more localised to the right leg. Dr. F. H. Low saw the case upon Feb. 6th and immediately sent it to the hospital. Two days after admission a swelling over the lower part of the back was noticed by the mother. The patient was a well-nourished child, cried when moved, and passive movement of the pelvis and legs elicited pain, the movement of the right limb causing more pain than the movement of the left. There was a swelling the size of half an orange over the right sacro-iliac synchondrosis. Its margins were diffuse and there was marked fluctuation. When the child cried it became very tense. No rectal examination was made. The temperature was 101° F. After a thorough purification of the skin of the lower half of the body an incision two inches in length was made immediately over the centre of the fluctuating swelling, ten ounces of pus were removed, and on digital examination of the cavity the fore and middle fingers could easily be passed through a jagged opening in the right sacro-iliac synchondrosis and into a larger cavity beyond that was limited in front by the anterior abdominal wall. The latter could be felt between the examiner's finger and the hand upon the surface of the abdomen. Both cavities were wiped out by sponges wrung as dry as possible out of a 1 in 2000 solution of perchloride of mercury and the wound was sewn up with horsehair. After the operation the child was much collapsed. The wound healed and on the eleventh day the stitches were removed. The pus was inoculated into a rabbit and a guinea-pig; the rabbit died and the guinea-pig recovered. Only diplococci and streptococci could be found upon examining in the same way as before; the cover-glass preparations were stained for tubercle bacilli, but the carbol fuchsine and sulphuric acid gave negative results. On the 18th a fluctuating swelling again appeared over the previous site, but no increase of tension could be detected upon the child crying. The temperature was 100°. An incision into this swelling only liberated serum and no pus. My forefinger could not be passed into the opening through the right iliac synchondrosis. The wound was again sewn up by continuous suture and did not further trouble the child or surgeon. The mother has had two or three alarms since and has brought the child up for examination, but the patient has remained up to the present time perfectly well The serum removed at the second operation was not examined.

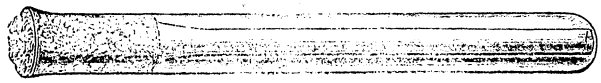
This was a case of severe local infection; the source of inoculation could not be detected. The disease probably began as an osteo-myelitis of the bones forming the right sacro-iliac synchondrosis. No antitoxin was injected.

The next three cases are those of mixed infection.

CASE 4.—A man aged thirty-five years was admitted to hospital on June 5th, 1896. The family and previous histories were of no clinical importance. He had not been conscious of being a subject of an infective disease for six years. Then he had an attack of gonorrhœa. The first thing noticed by the patient was that in August, 1895, his penis swelled and a small sore appeared on its dorsum; the sore gradually spread and eventually under treatment (which was of a doubtful nature) it healed. No further trouble was experienced until the end of January, 1896, when his penis again became swollen and another sore appeared near his frænum. The sore remained the same size for a month when it rapidly grew larger and a swelling appeared in the perineum and up the fold between the thigh and perineum. A swelling also appeared in the groin of the left side; this was freely opened, but eventually became a large foul-smelling ulcer. In May lumps appeared in the tibiæ that gradually became quite soft. On admission the urethra was found to be laid open for an inch of its extent, and a ring of skin at its base was the only part of the penis with a cutaneous covering. A large sore with undermined edges and the size of a man's hand was situated above Poupart's ligament. In the right groin was another large abscess; an abscess was also discovered on the dorsum of the right foot. These swellings were opened on June 16th. Fluctuating swellings over the forearms were opened and pus was removed for examination in the same manner as before. Only streptococci could be stained upon the cover-glass preparation; a white growth in two or three days occurred upon all the tubes, but the gelatin was rapidly liquefied; stroke cultivations were made upon gelatin, but all the growth that could be seen liquefied the gelatin and still only streptococci were stainable, and the rabbit inoculated with the pus did not die, but recovered after being very ill for twenty-four hours. (In recently describing the case to an authority it was definitely decided by him to be a case of mixed infection of streptococcus pyogenes, and that plate cultivations ought to have been made instead of the stroke cultures with a view of determining the organism that liquefied the gelatin.) After the operation the large sore in the left groin was more efficiently examined and the forefinger was passed directly downwards and inwards towards the base of the bladder. A catheter was then passed into the bladder, but no communication could be detected between the great cavity in which was the finger and the bladder or urethra. The digital examination caused profuse hæmorrhage, but it was easily controlled by pressure. The No. 12 catheter passed with the greatest ease. In examining by the rectum nothing definite could be detected; rather than any tumour, the parts outside seemed to be more ulcerated. After this examination the patient passed blood in some quantity by the urethra with the urine, but urine without blood escaped from the groin ulcer, a large quantity a day. In the urine passed per urethram were large epithelial cells containing pigment granules. The case was undoubtedly one of extravasation of urine, and, I thought, probably due to the ulceration of malignant disease at the base of the bladder and prostate, and the extravasation the source of the mixed infection. During the whole of this time his temperature varied between 98° F. in the morning and 103·6° at night. Fortunately there was no frequency of, or pain on, micturition, and in the patient's condition it was not thought justifiable to do more than carefully dress his groin and other wounds. No further collection of pus occurred until July 13th, when the skin over the malar bone of the right side was seen to be swollen and fluctuation

Hosted by Google

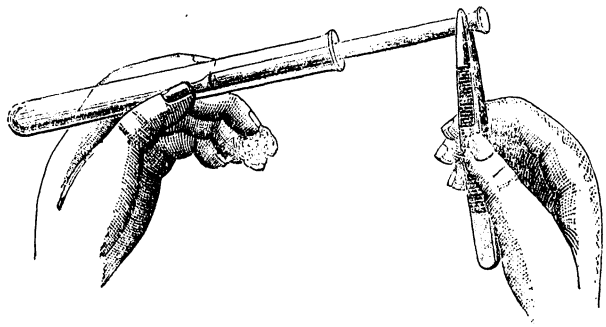
was obtained. This abscess was opened by Mr. Wilmer. To try to eradicate the streptococcus element from the case it was decided to inject the antitoxin, so with the patient's consent on the 16th 10 c.c. of the serum were injected. The temperature remained about the same as before (99° in the morning and 102° at night). On the 17th during the day three injections of the antitoxic serum were made, each of which was of 10 c.c. The evening temperature was still 102°. On the 18th, in the morning another 10 c.c. of serum were injected, but still the patient was not showing any sign of improvement. On the 19th an abscess was noticed on the right frontal eminence and another over the skin of the right tibia, both of which were opened and 20 c.c. of serum were injected. On the 20th, upon the advice of Dr. W. Bulloch a larger dose of 75 c.c. of the serum was injected, but the temperature and general signs continued to get worse. The opened abscesses did not in any way give rise to further trouble, neither were there any complications at the seats of the injections. The patient died on July 26th. The relatives would not allow me to determine the cause of the extravasation or to examine the blood and various viscera for bacteriological evidence. In all 140 c.c. of the anti-streptococcic serum had been injected.



CASE 5.—A girl aged sixteen years attended as an out-patient at the West London Hospital in August, 1896, with facial erysipelas. A small bleb under the left eye was cauterised and cover-glass preparations were made of the contained serum, and a gelatin and a potato tube were inoculated. There was a yellow growth on each. The gelatin was liquefied and plate cultivations showed diplococci, streptococci, and staphylococci. The cover-glass preparations of the pus showed the same when stained. The patient had been ill two days. Upon the first day of her attendance 10 c.c. of the serum were injected. On the next day the rash had spread to the front of the forehead into the scalp and over the nose and chin, the temperature being 101° F. A dose of 20 c.c. of serum was injected. On the following day the rash was still spreading; the temperature was 102°, and 30 c.c. of serum were injected. On the fourth day the rash had spread still further, involving the neck and forehead, and no more antitoxin was given, but the face was getting better. No seat of inoculation was to be discovered. As the disease seemed to be running its usual course and the 60 c.c. of the antitoxic serum did not appear to influence it no more injections were made.

CASE 6.—A girl aged eighteen years was admitted to the West London Hospital on Sept. 18th, 1895. Her family history was unimportant. Since childhood the patient had had a discharge from the right ear. For the previous three weeks she had complained of pains in the head and occasional attacks of vomiting and shivering. The mother stated that for the last three days the patient had been light-headed. On admission her temperature was 102°; she was delirious; there were double optic neuritis and an œdematous, fluctuating, crepitant swelling extending subcutaneously from behind the right ear over the temporal and mastoid regions. Three-quarters of an hour after admission the patient was anæsthetised, and I made a semi-circular incision behind the right ear and upwards to the temporal region and downwards to the mastoid region. From the centre of the incision another was made directly backwards and therefore at right angles to it. The flaps thus made were turned up and down. By these procedures most offensive pus was liberated. No opening into the so-called mastoid antrum could be seen so an opening was chiselled into it; out of this cavity sprang up, as if under pressure, some more offensive but thicker pus. The mastoid process was also chiselled open and pus was scraped away together with the infiltrated cells of the mastoid process. Chiselling still growths back the lateral sinus was well exposed, and as this venous channel was evidently thrombosed it was freely opened upwards and downwards and the same offensive and semi-purulent contents were removed. The limit of the clot was reached in the upper end but not in the lower. The internal jugular vein was next exposed and ligatured and an inch of it excised at the level of the upper border of the thyroid cartilage. No thrombosis had reached this point. She made an uninterrupted recovery. There was no facial paralysis. Stained cover-glass preparations and stroke cultivations made on agar, gelatin, and potato from the blood clot from the lateral sinus demonstrated a very mixed infection of streptococci, staphylococci, and various kinds of bacteria. No antitoxin was administered. I saw the patient last on Sept. 27th, 1896. She was perfectly well with the exception of a slight discharge from the ear. The big hole behind it had to a great extent filled up with bone.

With regard to the cases injected with the antitoxic serum it will be seen that the disease was well advanced in all of them before the antistreptococcic serum was administered. This point is important, and had these cases been treated by the serum quite early, their results might possibly have been different.



By means of a sterilised test-tube alone it is impossible to collect pus or other fluid without soiling its upper part, thereby setting up connexion that may lead to the contamination of its contents. To eliminate this source of contamination I now use the simple apparatus depicted in the figures. It consists of two parts—an inner or conducting tube, which is only a piece of glass tubing open at the ends and its top made into the shape of a small funnel, placed into an ordinary test-tube and fixed *in situ* by means of the cotton-wool plug with which this tube is stopped (Fig. 1). This precaution is of importance, for unless the

FIG. 1.

inner tube is fixed it will shake about while travelling and crack its host. The whole thing is sterilised together. Fig. 2 demonstrates its method of use. The cavity containing the fluid is opened at its most accessible spot by means of an incision most conveniently directed and its walls are held apart by blunt hooks; the inner or conducting tube is then drawn half-way out of its host and by

FIG. 2.

means of a pair of forceps is held in the cavity at an angle that will permit the fluid to gravitate through it to the bottom of the receiving tube. When a sufficient quantity has been collected the inner tube is carefully and permanently removed, and the tube containing the fluid must be again stopped with its sterilised cotton-wool plug.

Harley-street, W.

A CASE OF ACROMEGALY.

BY ISAAC BANKS, M.D. R.U.I.

I THINK the following case will be of interest especially considering its rapid progress. The patient is a woman aged twenty-six years who has been married four years; she is a nullipara. She has led a regular life and has never had any illness that she can remember except an attack of scarlet fever. Her family history is good, there being no hereditary complaints and no specific history. About eighteen months ago she began to suffer from intense pains in her head, eyes, and legs; the head pain was continuous and most marked in the frontal and occipital regions. The pain in her eyes she described as affecting "the back of her eyes," especially the left, and was increased on movement. The pain in her legs was intermittent; it was most marked in the lower half of both tibiæ and gave the sensation as if her "bones were bursting." She had not menstruated for two months and thought she was pregnant. Her hands

Hosted by Google

commenced to swell so that she had to remove one of her rings, and at the same time her boots, which previously were bought ready-made "fives," had to be got to order owing to the increased breadth of her feet. At the same time her hair became much coarser and longer. She came under my treatment nine months ago, having never had previous medical attendance. Her relatives attributed all her symptoms to pregnancy and her mother wished me to examine her for this. Fig. 1 is reproduced from a photograph which was taken three years ago, the other two showing her condition when she first came under my care. Her present condition is as follows. Her face is elongated, oval in form, measuring from the frontal hair to the symphysis menti 9½ in. The left malar bone is very prominent and the left eye appears as if pushed upwards by it. The expression is dull and lethargic. The optic axes are convergant and proptosis of both eyes is well-marked, but both these symptoms vary from time to time. Both eyes are hypermetropic, but the vision varies with the degree of proptosis present. Central vision is lowered in the left eye and the optic papilla is of a pale pink colour; the right eye

FIG. 1.

Shows an active energetic young girl three years before she came under my notice.

has well-marked temporal hemianopia. The eyelids, lips, and nose have a thickened, œdematous appearance; they are firm to the touch and do not pit on pressure. She breathes through her mouth, which is always open. The Schneiderian membrane is hypertrophied. The lower jaw takes part in the general enlargement of the bones of the face and measures from condyle to condyle 14¾ in. When the mouth is closed the upper and lower incisors meet, but the latter do not project. The skin is of a sallow colour, moist, and without pigmentation. At times there are profuse perspirations. The temperature at different periods has been 97·4°, 99°, 98°, and 100·4° F. The tongue and the soft palate are hypertrophied; speech is slow, clumsy, and thickened. The neck is greatly enlarged, especially about the origin and lower portion of the sterno-mastoid. So far as can be determined the thyroid body is normal; there is no evidence of increase in size or persistent thymus. The scapula and the bones of the shoulders are normal, but the sternum is broad and elongated, especially at the junction of the manubrium and the gladiolus, where there is a thick prominent ridge, as can be seen in Fig. 2. The second rib is also prominent and thickened. The breasts are atrophied, and particularly the nipples, which are surrounded by a few coarse long hairs. The cervico-dorsal curve is well-marked — a true kyphosis with no lateral deviation. The abdomen is extremely pendulous, with transverse folds at and below the umbilicus; the girth at the umbilicus is 45½ in. Her waist has increased by 15 in. during the last two years. The splenic dulness seems increased, so far as could be made out; the lower ribs are very oblique and almost touch the iliac crests. The pelvic bones are not enlarged. The hands are greatly enlarged; she has been unable to wear gloves for about two years, and her wedding ring, which was much too large, cannot now be removed from her finger. This enlargement is entirely in breadth and thickness and of the whole hand. The circumference of the forefinger over the middle of the proximal phalanx is 3½ in., that of the thumb at a corresponding point being 3¾ in. The fingers do not taper; the nails are longitudinally striated, broad, thin, and brittle. The palmar folds are well marked; the thenar and the hypothenar eminences take part in the general enlargement, and the entire hand is firm and resistant to the touch.

FIG. 2.

Shows the cervico-dorsal curvature, the pendulous abdomen, and the ridge at the junction of the first and second pieces of the sternum.

There is no loss of strength. The enlargement of the feet is characteristic, but not so well marked as that of the hands. The circumference at the metatarso-phalangeal joint is almost 10½ in. The tibiæ are tender on pressure. The muscles of the arms and the legs are lax and flabby—she says "wasted"—but they do not appear so. The patellar reflexes are absent; the superficial reflexes and the cutaneous sensibility are normal. Her gait is clumsy and she cannot stand erect with her eyes shut. The circulatory and respiratory systems are normal, though at times the breathing is laboured and a little irregular; the appetite is fair, there is extreme thirst, and obstinate constipation is present. The mental condition resembles that characterising myxœdema. She sleeps for twelve hours out of the twenty-four; she appears to suffer from slight sensory aphasia; her memory is at times deficient—she will ask the time repeatedly in the course of an hour. The condition of the genito-urinary system is as follows. She passes in the twenty-four hours from five to seven pints of urine of a specific gravity of 1020 and containing a large quantity of

Hosted by Google

phosphates, but otherwise normal. The hair over the pubes is coarse and thick and its distribution is similar to that in the male, being continued upwards to the umbilicus and backwards past the anus; these changes in quality and distribution have developed within the last two years. The external genitals are normal; the vagina is elongated, large, and patulous, easily admitting three fingers. The uterus is small, atrophied, and apparently not larger than a hazel nut. The sound passed a little less than two inches. The ovaries could not be felt. No sexual gratification had been experienced for more than a year.

FIG. 3.

Shows the formation and expression of the face, the condition of the hands, the strabismus, and the upward displacement of the left eye.

The patient has now been under treatment for three months. This consists of one ounce of sulphate of magnesia every second day and a mixture of ten grains of iodide of potassium with twelve grains of bromide of potassium thrice daily. Under this treatment her mental state has materially improved; she sleeps less, her memory is better, and she is able to perform most of her household work, but otherwise her condition is unaltered.

The most noticeable peculiarities of this case are its rapid progress, the change in quantity, quality, and distribution of the hair and the hypermetropia seemingly dependent on the proptosis.

Aberdare.

THE PATHOLOGY OF ECLAMPSIA.

BY JOHN W. BYERS, M.A., M.D,
PROFESSOR OF MIDWIFERY, QUEEN'S COLLEGE, BELFAST.

IN the whole range of obstetric medicine there is no more interesting or fascinating subject than eclampsia and certainly none which presents such a variety of questions for discussion. The physician knows so little of the natural history of eclampsia that he cannot predict the course of any case either with or without treatment. He knows that a great many of the cases are associated with albuminuria and diminution in the amount of urea excreted. He also observes that the condition is most frequently seen in primiparæ, that its occurrence varies in different parts of the same country and in different years and seasons, that when it sets in during pregnancy it is most frequently met with towards the latter months of gestation, but that it is more often encountered at labour and less frequently after the birth of the child. Further, he knows that various post-mortem lesions are met with in the kidneys, liver, lungs, and brain. The clinical history and the morbid anatomy vary in different cases, and there is no condition in which the medical man finds his grounds for prognosis less sure, for, as Professor Tarnier stated at the late International Congress of Obstetrics and Gynæcology at Geneva, eclampsia is a disease full of surprises, cases the most benign in appearance frequently turning out badly, while, on the other hand, the very reverse is often true.

If the treatment of eclampsia is to be at all scientific, if it is to be anything more than merely empirical, it must be based upon some sound knowledge of the causation of the condition with which the physician is called to deal; but before discussing the various views put forward as to the origin of eclampsia I would like to speak of a point of great importance, to which, at least in these countries, too little attention has been paid in considering the cause of eclampsia, and that is the part played by the fœtus. It is surely a very noteworthy circumstance, which personally I have now verified on several occasions and to which notice was first drawn by Winckel, that when the fœtus dies during pregnancy, even in the case of a woman who has what we term the premonitory symptoms of eclampsia, the danger for the mother is entirely overcome or very much diminished. I called attention to this point in a paper at the Geneva Congress introductory to the question of the Treatment of Eclampsia, and in the discussion which followed Professor Morisani (Naples) and Professor Pasquali (Rome) referred to it, the former stating that before deciding on obstetrical intervention it was necessary to ascertain whether the child was alive or not, as he had on several occasions proved that the death of the fœtus put an end to the convulsions and the albuminuria; while Dr. Pasquali said he had found that the death of the child checked the eclampsia, and he confirmed the view put forward by me by stating that this fact suggested the question whether the fœtus does not play an important *rôle* in the etiology of such a dangerous complication. It is known also that in multiple pregnancies there is a greater predisposition to convulsions, and, finally, while the maternal mortality is greatest when the eclampsia sets in during pregnancy, it is less when that complication occurs during labour, and least of all when it occurs for the first time after the birth of the child. It must not be forgotten that the fœtus in its development forms excrementitious or waste products, which must be eliminated by the mother in addition to what she has to get rid of as the result of metabolism in her own system. Various views have been put forward to account for the origin of eclampsia, but they may be grouped under three heads:—

I. *The reflex neurosis theory.*—According to some teachers the uterine nerves are, owing to the enlargement and contraction and retraction of the uterus, kept in a state of irritation which reflexly acts on the renal and sympathetic nerves, causing the albuminuria and the eclampsia; while others teach that the convulsions are reflex, but culminate in a cerebro-spinal centre in close proximity to the albuminuria centre. There are three objections to such an explanation of eclampsia: (1) there is no evidence in support of it beyond the circumstance that the nervous system in pregnancy and during labour is in a condition of high tension or increased irritability; (2) this view fails to explain the post-mortem lesions present in fatal cases; and (3) if the whole phenomena of eclampsia are to be regarded as merely reflex, why do they not occur in every pregnant woman who has a highly-strung nervous system? Reflex action may be a factor in the problem, but it certainly will not explain the whole question.

II. *The kidney view.*—Ever since the time that Lever, in 1842, made his brilliant discovery that in many cases of puerperal eclampsia there is albumin in the urine, the attention of obstetricians has been fixed on the kidneys, and the view has for long held the field that the convulsions are caused by the poisoning of the nerve-centres by certain by-products, urea, creatin, &c., which the kidney, owing to its abnormal condition, fails to eliminate. The arguments in favour of the kidney theory are:—1. In eclampsia the condition of the urine clinically indicates some decided interference with the function of the kidneys. It often contains albumin, blood, renal epithelium, and casts. It is scanty, and at times there is a history of its sudden suppression, and, as Dr. Herman has pointed out, the most constant feature in these cases is diminution in the excretion of urea during the fits. Œdema of various parts

Hosted by Google

of the body is noted, and in certain cases ophthalmoscopic examination demonstrates changes in the fundus oculi. 2. The results of post-mortem cases show that often a diseased condition of the kidneys is present, and Professor Leyden thought there was a nephritis specially associated with pregnancy and distinct from all others. He found the kidney in three fatal cases "large and pale, the cortex yellowish and dull. Microscopic examination showed a very extensive loading with fat, especially in the tubuli contorti; to some extent also in the glomeruli and in the Malpighian capsules. The fat was distinctly present in large drops." When the kidneys had remained for a time in spirit the fat in great part disappeared, and then the organs, on microscopic examination, appeared to be normal, and accordingly he inferred that this fatty condition was not a degeneration but an infiltration. His view was that such morbid conditions are due to a prolonged arterial anæmia and that they explain the rapid recovery which so frequently follows delivery. This extreme view that all cases of eclampsia are the result of renal disease is, I think, being abandoned, and the following facts are distinctly against the renal theory of the causation of eclampsia. 1. Every obstetrician now and again comes across cases of this complication in which no albumin has ever been present; nay, even, in some fatal cases, the kidneys are quite healthy. 2. All obstetricians have seen women with chronic renal disease become pregnant and yet never develop convulsions. 3. It is also remarkable that the certainty of the occurrence of eclampsia is not proportionate to the intensity of the albuminuria. 4. It is very rare for convulsions to occur in acute disease of the kidney apart from pregnancy, except in cases where the renal affection is associated with some specific disease like scarlet fever, where there is *already* a poison circulating in the blood. 5. Again, sometimes women die comatose in eclampsia, and yet the amount of albumin present has never been more than a trace. I believe albuminuria is of the utmost importance as a predisposing factor, but I do not think it is the exciting or sole cause of eclampsia.

III. *The toxæmic or blood-poisoning hypothesis.* — As neither of the two previous views covers all the cases of eclampsia, and as serious objections can be brought against them both, modern observers have been inclined to take a broader view of the causation of eclampsia; and the opinion held by many obstetricians at present may be stated in this way. Taking everything into consideration, the most probable explanation of eclampsia is that the convulsions are caused by the action on the nerve centres of a poison which arises as a product of ordinary tissue metamorphosis (elaborated in part by the mother and also by the fœtus), and which, provided it does not accumulate in too great an amount and that the eliminating organs are working properly, is got rid of without any ill effects. If, however, any of these organs (especially the kidney, liver, and intestines) gets too much to do—as when the muscular efforts of labour increase the work of the kidney—then the poison is not eliminated and its increased accumulation affects the nervous centres; or the same thing may occur if the function of the excreting organs is interfered with, as in constipation, or when the kidney is in that condition which Leyden has described as being peculiar to pregnancy, or when there are changes in the renal organs and the liver in the form of a parenchymatous degeneration, produced it may be by the poison in its circulation through them. It is in this way that the presence of albuminuria is of such importance clinically. The high tension and increased irritability of the nervous system in pregnancy and labour and the presence of a source of peripheral irritation in the uterus are also elements of great importance in the problem. This theory of blood poisoning or toxæmia as the cause of eclampsia is supported by the following arguments:—1. It covers all the cases whether there is albumin or not present. 2. The clinical history of eclampsia is that of a toxæmia. "The prodromata," as Kaetenbach puts it—"gastric and cerebral symptoms—the rapid occurrence of serious disturbance in the action of the brain, the post-mortem increase of temperature, the nature and frequency of nerve disorders that follow and which find their analogy in the neuroses consequent upon typhus and diphtheria probably caused by toxalbumins, are scarcely to be explained unless by the theory of blood poisoning."[1] 3. The post-mortem appearances. According to Zweifel[2] multiple thromboses are invariably found in the liver, lungs, and brain in all fatal cases of eclampsia and certainly indicate the existence in the circulation of some blood-coagulating product of organic change—it may be creatin, suggested in 1853 by Wieger and Schottin, and, more recently by Landois, some leucomaine or carbonic acid. Zweifel mentions that the inoculation of creatin into the cortical cerebral matter of apes caused clinical symptoms like those of eclampsia. Chambrelent of Bordeaux showed in a series of experimental researches that the toxicity of the blood is increased both in the fœtus as well as in the mother when the latter has presented symptoms of eclampsic intoxication; and it is worth noting that Professor Tarnier has stated that the better results in his treatment of eclampsia from 1892 until 1896 (when he had twenty-two cases of convulsions with two deaths—a mortality of 9 per cent.) were due to the new treatment he adopted based on Dr. Chambrelent's researches on the toxicity of the blood in eclampsia. At the Geneva Congress Professor Lindfors (Upsala) showed microscopic sections exhibiting changes in the liver cells and also emboli proving the existence of hepatic cells in the floor of the cardiac cavities from a woman dying from eclampsia.

Such is the modern view as to the causation of eclampsia, and considering the extraordinary progress of bacteriology there have not been wanting some to suggest that the ultimate cause of the blood-poisoning is the entrance of bacilli, but up to the present these have not been discovered and all the phenomena of eclampsia can be explained as due to an auto-intoxication. This toxæmic theory is of the utmost practical value, because, acting upon it as a good working hypothesis, it assists the physician in the prophylaxis of eclampsia. It teaches him the enormous importance of the eliminating organs in pregnancy, and when these show any sign of not acting properly he at once puts the patient on a diet such as milk, which gives them the least to do, and which French observers think has the power of getting rid of a quantity of the toxin; and also by hot baths and purgation he encourages these organs to act and so to eliminate the poison.

NOTES ON BERI-BERI AS OBSERVED AT THE SEAMEN'S HOSPITAL, GREENWICH.

BY M. H. SPENCER, M.A., M.D. CANTAB.

BERI-BERI is a disease which rarely finds its way into the wards of a general hospital in England, but at the Seamen's Hospital, Greenwich, where patients are received from all parts of the world and of all nationalities, many instances of this disease come under notice. On referring to notes there appear to have been between thirty and forty cases of beri-beri treated in this hospital during the two years 1890 and 1891. The diagnosis in many or most of the cases was "œdema of legs" or "peripheral neuritis," but the description of them leaves but little doubt that they were cases of beri-beri. During my residence in the hospital from January, 1891, to August, 1895, I saw a good number of these cases, but amongst them only one which terminated fatally. I believe that the form of the disease that we see in England is the sub-acute variety, for in the countries where the disease is endemic it is extremely fatal. The average duration of our cases after they came under treatment was about two months. The majority of the patients were Lascars or Zanzibari; a few were Chinamen. Beri-beri is very common in China, but the Chinese form a small proportion of the ships' crews visiting England. As a rule, owing to the difficulty of understanding the patient's language, we got very incomplete histories or none at all. Even those who can speak Hindustani can make little of the Lascars, who generally speak a dialect of their own. In most cases, however, the diagnosis is not difficult even when all verbal communication between medical man and patient is impossible. One cannot help regretting that in many cases the observations with regard to sensation are incomplete, and in other cases where a history might have been of considerable value in clearing up the case, the diagnosis had to be written down with a decided query in front of it.

I do not intend in this paper to introduce long case narratives, but to confine myself to a brief sketch of the disease, illustrated by the chief symptoms which presented themselves in the cases that were under treatment at the

Hosted by Google

Seamen's Hospital, Greenwich. Nearly all observers now agree in regarding beri-beri as a disease of the peripheral nervous system. All the symptoms which are observed in the course of the disease are accounted for by this view, and it has been established, moreover, by microscopical examination of the nerves in fatal cases. The symptoms arising from a diffuse peripheral nerve lesion are, of course, varied, and they are seldom all present in a given case. The muscular, sensory, circulatory, respiratory, and digestive systems are all liable to be affected, and it will be convenient in giving a sketch of the disease to consider the symptoms it presents in this order.

The muscular system.—Loss of power in the limbs was present in all cases. The legs were always affected more than the arms. The paralysis was never absolutely complete and it varied much in degree, but in most of the cases when first seen the patient was unable to stand alone without assistance. When tested electrically the reaction of degeneration was generally present. The muscular wasting in chronic cases was very marked, the legs often being reduced to mere sticks. When the patient recovered sufficiently to be able to walk a little the gait was very tottering and slow. In some of the cases it was rather spastic in character, the feet being lifted high from the ground. In most cases the toes were placed upon the ground first, but in one case the heels were brought to the ground first, as in ataxy. Dr. Manson in speaking of the gait remarks: "The patient has to raise the heel very high before he can clear his toes from the floor on advancing the foot. This is due partly to imperfect perception of the ground, partly from the foot flexors being weakened, partly from a certain amount of semi-spastic contraction of the calf muscles. On the foot being placed upon the ground again the toes are seen to be the first to touch it, the sole and heel falling with a flop. If the flexors of the leg and thigh become seriously involved the foot cannot be raised and the gait becomes a shuffle." As in alcoholic paralysis, the extensors suffer more quickly than the flexors and foot drop is therefore a common phenomenon. The weakness of the arms in the cases I have seen was evidenced by feebleness of grasp, but never amounted to actual paralysis. The weakness of the legs and muscular wasting was generally, but not always, symmetrical on the two sides. The paralysis was never accompanied by loss of control over the emunctories. Laryngeal paralysis is said to be common. I saw one instance of marked aphonia, but could not get a view of the cords owing to the swelling of the fauces and soft palate. Ocular paralysis was never present. Cycloplegia was not tested for. It does not seem to have been noticed by writers. The order in which the muscles are attacked has been observed by Pekelharing and Winkler. The muscles supplied by the peroneal nerve are invariably the first to be affected, next the calf muscles, then the extensors of the knee, then the adductors and flexors of the thighs. When the thigh muscles are attacked the hand and wrist muscles, with the supinator longus, are nearly sure to suffer. The knee-jerk was absent in all the cases I saw; it may, I believe, be exaggerated very early in the disease, but is soon lost and is late in returning.

The sensory system.—Anæsthesia is, on the whole, a very constant symptom. It is often difficult to map out at all accurately anæsthetic areas for reasons given above. In a greater or lesser degree it was present in nearly all the cases that I saw, and I have no doubt that if seen early enough and tested carefully every case would have shown some change or loss of sensation. Pekelharing says that the groin and neighbouring surfaces always retains sensibility. Simons found numbness round the mouth to be a common symptom in Japanese beri-beri. The chest appears to be seldom affected. In some of the cases I saw the anæsthesia was general, the lips only retaining their sensibility. The most usual seats of anæsthesia were the lower extremities, especially over the anterior surface and the tips of the fingers. When admitted a patient could seldom perform the rough test of picking up a pin between the thumb and index finger. The return of sensation took place, as might be expected, far more rapidly than the return of power. Hyperæsthesia is as constant a symptom as anæsthesia. Tenderness of the muscles was present in all the cases I saw; it varied in degree; the parts most sensitive to pressure were the calves of the legs and thenar and hypothenar eminences; in some cases tenderness was very marked over the front of the tibia. Besides tenderness painful cramps are present at times in the muscles. There is often tenderness over the nerve trunks. Precordial and epigastric pain is sometimes complained of, with a sense of constriction and oppression in the latter region.

The circulatory system.—Anæmia is present in many of the cases, and by some authors the disease has been put down to anæmia, and has even been considered to be identical with pernicious anæmia or ankylostomiasis. It must be confessed, however, that anæmia may be absent and that the whiteness of the œdematous skin is in some cases mistaken for anæmia. The hæmoglobin percentage falls in some cases to a little below normal, but leucocytosis is not present, and it is probable that the heart symptoms which are so often present are not the result of anæmia, but of a degenerative change of the pneumogastric nerves. The pneumogastric and phrenic nerves were particularly noticed by Pekelharing as those which generally showed signs of pathological changes in fatal cases. The presence of the ankylostomum duodenale is a coincidence, not a cause of the disease; it must be remembered that it is of frequent occurrence in Orientals. Dilatation of the heart was observed in most of the cases. Pulsation of the veins in the neck with enlargement of the area of the heart's dulness to the right often showed that the right ventricle had unusual strain thrown upon it, and this, as we shall see, is one of the dangers which have to be met and treated in severe cases. Absolute dulness in one case extended beyond the right edge of the sternum, whilst the apex beat was outside the nipple line. The cardiac impulse was often feeble and diffused. Murmurs were frequently, though not invariably, present. In several cases a loud systolic bruit was present at the apex partly conducted to the axilla. A systolic murmur over the base of the heart was more frequent. The second sound was frequently reduplicated and this sign was present in several cases in which the murmurs were absent. As convalescence was established the murmurs and cardiac dilatation subsided. The pulse was rapid, feeble, and irregular in most of the severe cases. It was always more rapid in the erect posture and on exertion of any kind. The rapidity of the pulse of a patient who was at rest in bed was looked upon to some extent as an indication of the severity of the disease even in the absence of other bad symptoms, and on the whole I think this opinion was justified. Œdema was present to some extent in the great majority of cases, and in some of them it was very marked. In two cases the œdema was of the hard variety, but before many days had elapsed the parts began to pit on pressure. Occasionally the whole body, trunk, limbs, and face were œdematous, giving to the patient the appearance of one suffering from an attack of acute nephritis. In one case there was considerable swelling of the soft palate and fauces. When the œdema was slight or disappearing it could generally be recognised by some pitting on pressure over the front of the shins, crests of the tibiæ, and front of the sternum. The œdema generally subsided quickly under suitable treatment. Dr. Manson says the œdema may be confined to certain spots, being localised at times to one limb; it may migrate from one part to another. In one type of the disease it is the most striking symptom. Pekelharing and Winkler lay great stress on pre-tibial œdema as an early sign of the disease; if in these cases the electrical reactions of the leg muscles are tested some definite changes from the normal type will, they say, be almost certainly found and a diagnosis be established. Albumin was only found in the urine in one of the cases that I saw. The œdema in this case was very marked and more persistent than usual; this case might have been diagnosed as Bright's disease but for the paresis, subsequent wasting of the muscles, anæsthesia, and localised tenderness. Ascites was not present in any of the cases; it seems to be of uncommon occurrence. The same remark holds good of hydrothorax. It is exceptional, Dr. Manson says, to meet with cases of extreme œdema, which render the patient completely waterlogged.

The respiratory system.—Dyspnœa is a frequent symptom in beri-beri. It may be paroxysmal in character and resemble the dyspnœa met with sometimes in influenza apart from lung complications. This form of dyspnœa was noticed by Graves in the influenza epidemic of 1839, and was no doubt of nervous origin; a similar explanation is probably applicable in beri-beri. When the right ventricle is seriously dilated and hampered in its action a severe form of dyspnœa with cyanosis results, and apart from this form dyspnœa of cardiac origin from failure of the heart's action may be present, accompanied by great epigastric pain and oppression. I saw one instance of this form of dyspnœa in a Chinaman who

Hosted by Google

died from the disease soon after admission. The diaphragm or intercostal muscles may be paralysed and thus cause death from interference with the respiration. Besides these nervous and cardiac forms dyspnœa may arise from œdema of the lungs. Some œdema of lung is not an infrequent complication, as evidenced by cough and expectoration of watery, frothy sputum. In the fatal case above mentioned the lungs were very œdematous and the heart was dilated with soft, friable muscle wall. In most cases there is a certain amount of breathlessness on exertion.

The digestive system.—Together with the other organs supplied by the pneumogastric nerve the stomach is liable to suffer. In one case under treatment vomiting was a prominent symptom, but as a rule it is absent. Diarrhœa was present in one case only and was easily checked. Dr. Manson mentions it as not an infrequent symptom at the commencement of the disease.

Temperature.—In the cases we had under treatment the temperature was normal or subnormal throughout. There is a period in the disease at its commencement when the temperature rises to 103° or 104° F., preceded by a rigor; it soon, however, falls to normal. This fact was observed by Dr. Manson during an epidemic which occurred in hospital. I do not think, however, that a rise of temperature at the onset of the disease is a constant symptom. The onset in many cases is most insidious.

Etiology.—In spite of the arduous researches of Pekelharing, Winkler, and others the organism which is the cause of beri-beri has not been satisfactorily and certainly determined. But little doubt, however, remains that it is a germ-borne disease and that the micro-organism which is the cause of it has a specially toxic influence upon the peripheral nerves. Europeans residing in endemic areas but seldom suffer owing to their habits being different to those of the natives. There was an epidemic of beri-beri, however, amongst the British troops in Burma in 1824, so that it is not a "race disease." Takaki believed it to be due to absence of nitrogen in the diet, and after this defect was altered beri-beri almost disappeared from the Japanese navy, but at the same time the hygienic conditions of the ships were greatly improved. Overcrowding seems strongly to predispose to the disease, but it occurs, as Dr. Manson says, not "from overcrowding but in overcrowding." It is certainly more prevalent in some ships than others, owing no doubt to the forecastles in which the crews live becoming infected. It may spring up at sea long after the ship has left port. The incubation period is a long one in some instances, and a slow poisoning may precede acute manifestations just as with alcoholic neuritis. Damp and heat seem to be predisposing causes. It is more common amongst men than women; amongst women pregnancy and the puerperal state have been mentioned as predisposing to it. The most susceptible period of life seems to be between twenty and thirty years of age.

Pathology.—Degeneration of the nerves was discovered in eighty-five successive necropsies made by Pekelharing and Winkler. The microscopical examination of the nerves showed great increase in the number of the nuclei in the endoneurium and often a proliferation of nuclei of the blood-vessels of the nerves. The medullary sheath was destroyed especially near the nodes of Ranvier. The myeline sheath was aggregated into shining granules. At a more advanced stage it disappeared and at a later stage even the axis cylinder was destroyed. In chronic cases there was hyperplasia of the endoneurium of a gelatinous character. The changes found in the cord were few and inconstant. Changes in the muscles of a degenerative kind were nearly always present to a greater or less degree.

Treatment.—Patients suffering from beri-beri should as soon as possible be removed from the infected area. They should be kept carefully at rest in bed in well ventilated rooms, which should be raised above the ground. Great care should be exercised in moving severe cases, for, as in scurvy, sudden heart failure is liable to occur. Treatment should be directed firstly towards strengthening the heart's action and towards the relief of the overloaded pulmonary system. For this purpose a mixture containing sulphate of magnesia, digitalis, and nux vomica seems to be useful. The sulphate of magnesia should be present in sufficient doses to secure free action of the bowels. In the meantime the patient's strength should be supported with suitable diet. Wheat, barley, or beans should be substituted for rice, and some animal food should be taken. Stimulants are best kept in reserve for attacks of syncope. If the right side of the heart is much dilated, as evidenced by pulsation of vessels in the neck, dyspnœa with cyanosis, increased area of the heart's dulness to the right, and reduplicated second sound, free purgation should be employed. Nitro-glycerine may also prove useful in such cases, but if relief does not follow these measures it is best to bleed the patient from the arm without delay. When the affection has reached a chronic stage, with wasting muscles, well applied massage and faradaism may do much to hasten recovery. During convalescence iron and arsenic may be given with advantage.

Geographical note.—In India the disease is met with in the Northern Circars, less frequently on the Coromandel coast, in the Carnatic, and on the Malabar coast. It is exceedingly prevalent in the Malay archipelago and Malay peninsula generally. It is present in Siam, Tonkin, Anam, Cochin China, and to a great extent in Japan. It is less prevalent in China than in Japan. It is present also in and around Calcutta, Assam, Aden, Zanzibar, Réunion, Mauritius, Nosibé, and Madagascar, the Congo and probably the West Coast of Africa generally, the Isthmus of Panama, Cayenne, Cuba, and Guadaloupe.

PHOTOGRAPHY AND CRIMINAL INQUIRIES.

BY SIR HENRY D. LITTLEJOHN, M.D., LL.D., F.R.C.S. EDIN.,
LECTURER ON MEDICAL JURISPRUDENCE, SURGEONS' HALL, EDINBURGH.

To render a medical report of a post-mortem examination as distinct and as easily comprehended as possible is no easy matter. Few possess the requisite skill, and our language, unlike the French, does not lend itself to definite expression. The highest praise that can be given to such an important document is to say of it that the party who reads it has as clear a notion of the injuries therein described as if he had been present and watched every stage of the dissection. Indeed, two different classes of readers have to be catered for—the strictly professional, who alone can fully estimate the value of the technical terms employed, and also those who cannot follow the intricacies of medical phraseology and who desire merely a plain statement as to the cause of death. Take, for example, a simple case of fracture of the skull. It is only a medical man who can intelligently follow the direction of such an injury, winding among the various cranial bones and at each step of its progress involving the use of uncouth names, the etymology of which is shrouded in mystery. In fact, it requires great descriptive power and a happy combination of scientific and popular phraseology to render such injuries intelligible to any but strictly professional persons. But if this is too often a matter of difficulty even to an experienced surgeon, what must it be to a juryman of average ability who towards the conclusion of an exhausting trial in court listens to a document bristling with the jargon of the schools? A judge has declared that the anatomical term, "sacro-iliac synchondrosis" had, like "Mesopotamia," a remarkably satisfying effect on his ear, but it certainly requires a considerable amount of explanation to render it comprehensible to the average mind.

Now, while accurate and clearly expressed reports are of importance so far as the prosecution is concerned, they become doubly so when the exigencies of the defence are considered. The Crown can by repeated precognitions possibly arrive at satisfactory explanations of the leading anatomical and other details mentioned in the medical report, but the defence, in the case of a poor client, has difficulty in obtaining medical assistance; and even when this is available the medical report—the basis of the charge—is too often so worded as to render it impossible even for a skilled witness to understand its full import. Details of most vital importance, as bearing on the causation of the fatal injuries, are too often so indefinitely expressed as to leave grave doubts as to their exact meaning. I have read such documents, full of sounding phrases and apparently teeming with accurate information, and yet which to the practised eye failed egregiously to supply the very information necessary to support the opinion expressed as to the cause of death. Indeed, it may be said that both the Crown and the

Hosted by Google

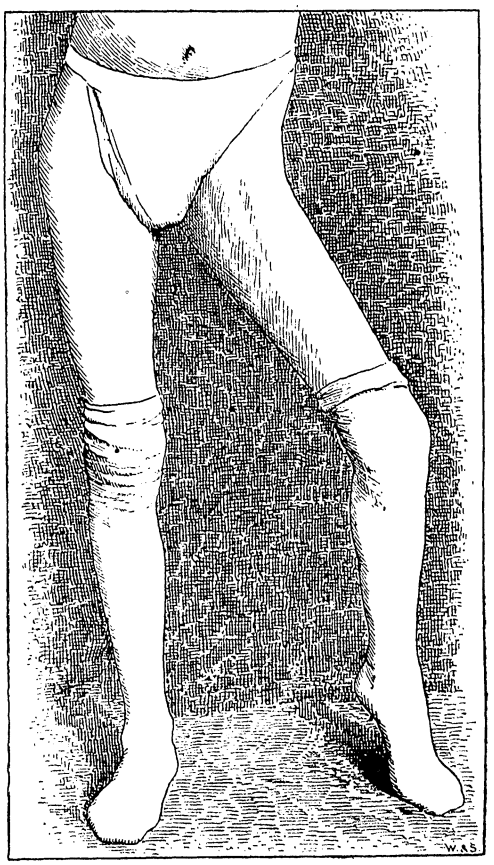
defence are at the mercy of the medical reporters, who, however honest and desirous of discharging their important duty, fail from want of experience and of power of expression to give a clear description of what was found on dissection. This, while specially to be feared in country districts where the opportunities for medico-legal practice are rarely afforded, is met with alike in town and country. I remember the first official dissection at which I was present. Associated with me was a senior member of the profession. It was a case of exposure of a newly-born infant. After what seemed to be an ordinary investigation, yielding no very definite results beyond establishing the fact that the child had survived its birth, it was luckily proposed to examine the throat, when a mass of soft dough was found accurately fitted to the upper strait of the air-passages and moulding itself into the interior of the larynx. This satisfactorily explained the death, and was described by my co-inspector, who dictated the report, as a "doughy mass in the pharynx." It so happened that at the time there was a public scare as to a new and formidable disease—viz., diphtheria—which, unfortunately, has never left us. Our report was read by the authorities as indicating death from natural causes, "the doughy mass in the pharynx" being looked upon as a graphic description of an unusual disease. But, in the language of correct description, "the doughy mass in the pharynx" became a mass of dough in that important cavity. The mistake was accidentally discovered; but in the detection of such a crime allow a few days to elapse and the best directed efforts of skilled officials are of little avail.

The remedy I propose for all this uncertainty is the more general use of photography. At present this is limited to the identification of the criminal, but with the unusual facilities now afforded for the practice of this popular art I hold that it should be extended to all departments of criminal inquiry. In the case just cited two photographs would have been of great interest—one showing the placid features of the deceased and the care that had been taken to shut the lips, the other representing the actual position of the foreign body occluding the entrance to the air-passages. Every county constable, in my opinion, should be provided with a camera, by means of which he could indicate with unerring accuracy the attitude of a dead body and its relations to surrounding objects.

The records of medical jurisprudence afford numerous examples of the importance of determining the position of the body and that of the weapon. This has frequently settled the question of accident, suicide, or murder. No doubt in our police regulations it is laid down that no dead body is to be moved until a medical man has inspected it; but in remote districts of the country, and even in our larger towns, medical assistance is not always available at once. A photograph in such circumstances would be invaluable and would put an end to discrepancies of otherwise trustworthy witnesses as to such simple facts as those connected with the disposition of a body. When the death has occurred in a house it might be of essential importance to determine the position of the body on a bed and its relation to articles on the bed or in the room. I need not insist on the benefit to be obtained in cases of murder and even in those of aggravated assault from at once taking a photograph of the *locus* before any of the furniture is moved, as one of the important questions in such cases relates to the presence of some article of domestic use which might furnish a plausible clue to the causation of some special injury. No doubt in such cases plans of the *locus* are in some instances implied and the furniture may be subsequently arranged as on the fatal night. The element of uncertainty, however, remains and might be avoided by the early use of the camera.

But I go further, and I urge, as a medical jurist, that in every important dissection the assistance of photography should be provided. I believe it was in the Monson case that it was first applied during successive stages of an actual dissection. The circumstances were peculiar. The body had remained for some time unburied, had undergone a long railway journey, and had been interred for nineteen days. Under these circumstances the skin quickly decays and is easily destroyed by a slight touch. Advantage was taken of photography to preserve the appearance of the flesh wound that existed on the neck and which indicated the size and direction of the original superficial injury. Another photograph determined with accuracy the extent of laceration to which the ear had been subjected, while a third showed the amount of shattering of the skull and a fourth the condition of the surface of the brain. Thus every stage of the dissection from without inwards was carefully followed and accurately delineated in circumstances of great difficulty. But although night had set in before the examination was finished the magnesium light afforded perfect definition in the various plates. Of course, the defence benefited by those illustrations and the medical report itself was in consequence much curtailed by simple reference to the various photographs, which were admitted as evidence and included in the list of productions in the case.

Numberless are the applications of photography to forensic medicine. A few of these I have alluded to. I am confident that while the detection of crime will be greatly aided by its use the administration of justice in its widest signification, as protecting the innocent and enabling the accused to bring forward every circumstance that can be urged in his favour, will be materially strengthened.



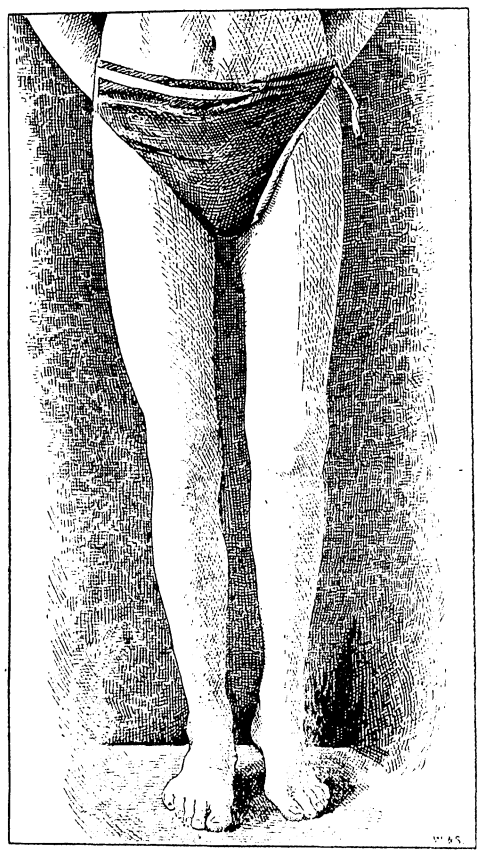
Edinburgh.

A CASE OF UNREDUCED DISLOCATION OF THE HEAD OF THE FEMUR INTO THE OBTURATOR FORAMEN TREATED BY EXCISION.

BY G. R. TURNER, F.R.C.S. ENG.,
SENIOR ASSISTANT SURGEON, ST. GEORGE'S HOSPITAL.

A MAN whilst at sea dislocated the head of the femur and was not treated till eight weeks afterwards at a hospital at Santos. Attempts at reduction were made, both with and without an anæsthetic, but unsuccessfully. On his way back

FIG. 1.



The position before operation. The patient could not, however, stand to be photographed without support, as was shown in the upper (omitted) part of the photograph.

Hosted by Google

to England reduction was again attempted under an anæsthetic with block and tackle. He was admitted into the Seamen's Hospital, Greenwich, more than three months after the accident, with the left lower limb considerably flexed and everted, the pelvis tilted and buttock flattened. The thigh could be flexed on the abdomen but could not be extended. Both internal and external rotation were limited to less than half their extent. The head of the femur could be felt almost in the perineum and the great trochanter about the centre of the buttock. There was shortening of one and a half inches, and when standing upright the great toe of the left foot did not quite touch the ground, the heel being drawn up and the foot everted (Fig. 1). The patient could only limp and hobble about with a stick. The head of the bone, which was found lying to the inner side of the obturator foramen, was excised on Feb. 18th, 1896. Several contracted bands of fascia and muscle in front of the thigh required division before the limb could be straightened. The head of the femur was found to be denuded of cartilage for about half its extent, and there had obviously been considerable damage done to the parts round the joint by the accident and the previous attempts at reduction. The present condition of the patient is satisfactory. He is able to walk about all day without pain or tiring and his leg is straight with his body. There is a little over two inches shortening, the limbs measuring thirty-six and a half inches and thirty-four and a half inches respectively (Fig. 2).

FIG. 2.

The position after operation. The patient stands alone and is very little inconvenienced by the two inches of shortening.

The scars in the perineum and groin are quite healthy. There is no movement at the hip and practically no eversion when the patient is lying down, though he throws his foot outwards a little when walking.

Green-street, Park-lane, W.

MEDICAL MAGISTRATE.—Mr. John R. Fox, M.B. Melb., has been appointed a Justice of the Peace for the Southern Bailiwick, Victoria, Australia.

A CASE OF SCARLET FEVER TREATED BY ANTI-STREPTOCOCCIC SERUM.

BY A. KNYVETT GORDON, M.B., B.C., B.A. CANTAB.,
ASSISTANT MEDICAL OFFICER, SOUTH-EASTERN FEVER HOSPITAL (METROPOLITAN ASYLUMS BOARD).

A VIGOROUS boy aged six years was admitted to the South-Eastern Fever Hospital on Nov. 17th, 1896, certified as suffering from scarlet fever. There was a history of vomiting and sore-throat on Nov. 14th, "rash all over" on the 15th, and nasal discharge on the 16th. On admission the boy was semi-comatose, the face was pale, and the respiration stertorous; the trunk and limbs were covered with a characteristic punctiform eruption, which was crimson in the groins but elsewhere dusky—almost purple, in fact; there was commencing desquamation on the face; the pulse was only just perceptible at the wrist and could not be counted. The tonsils and palate were much swollen and brightly injected; there was some viscid blood-stained mucus covering the mouth and fauces, but when this was cleared away the tonsils were seen to be free from any deposit. The temperature was 104° F. He was ordered milk and eggs only, with two ounces of brandy in the twenty-four hours. On the next day (Nov. 18th) the temperature varied from 103° to 101·5°, the pulse was very soft (140), and there was superficial ulceration of both tonsils, but less swelling and no deposit or sloughing. The heart and lungs were normal. On the 19th the temperature was 103°; the rash was not so dusky, and there was slight general improvement, the patient taking milk more willingly. There were well-marked urticarial wheals on the chest. On the 20th the child was much worse; the rash was very dusky, the fauces were dry and offensive, the ulceration was very slight, there was less swelling, and a little soft deposit on the ulcerated surfaces. The temperature was 103° and the pulse was 180. The heart was dilated to two fingers' breadth outside the nipple line and to mid-sternum; the first sound was very faint and there was no murmur. A fresh specimen from the fauces showed streptococci and staphylococci, no bacilli at all, and none on cultivation. There was diarrhœa. Ten c.c. of the *sérum antistreptococcique* of the Institut Pasteur were injected under the skin of the abdomen at 5 P.M. The brandy was increased to three ounces. On the 21st the temperature was 103° and the pulse 106 and much stronger; the fauces were less offensive, and there was less swelling. The heart extended from mid-sternum to just outside the nipple line; there was a better first sound. Another 10 c.c. of the serum were given at 12 noon. On the 22nd the temperature was 99·5°; the fauces were clean and not offensive; there was very slight swelling; the pulse was 96 and of much better tension. There was no urticaria, the scarlet rash was fading, and there was free desquamation. On the 23rd the temperature was 98° and the child was intelligent, answering questions, and hungry. He was ordered bread-and-milk and the brandy was omitted. On the 24th the left membranum tympani was red; there was a small perforation in the anterior inferior segment discharging odourless pus. The temperature was normal. He was ordered bread-and-butter and pudding. On the 28th he was sitting up in bed and had fish diet. On Dec. 2nd he was given mince diet. On the 3rd he was up in blankets and on the 12th he was up in clothes.

This case has seemed to me to be worth publishing on account of the rapidity with which the improvement followed the administration of the serum. On admission the child seemed moribund, but he rallied from the effects of the journey in the ambulance and commenced to improve a little till the seventh day of the disease; then he grew rapidly worse and was to all appearances dying from septicæmia. He was semi-comatose, with a failing heart, dusky rash, and diarrhœa. After one dose he rallied, and after the second a rapid improvement took place and was maintained, his convalescence occurring very much sooner than is usually the case with patients who have had any septic symptoms.

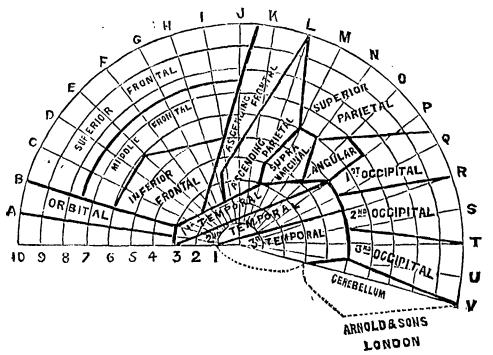
With regard to the indications for the use of the serum in scarlet fever, I would suggest that it would be valuable in any case that becomes septic, whether the signs exist from the first and are not in proportion to the severity of the throat symptoms—as in this case, where the throat was not

Hosted by Google

severely affected—or whether the condition is due to absorption from a sloughing throat or nose—the more common occurrence. In the latter case improvement often begins when the throat is vigorously attacked by constant swabbing with chlorinated soda or some other germicide, but I do not know of anything that has much effect when there is septicæmia with a moderately severe or even a mild throat. In this case the only drug given was brandy, and I do not think the remarkable improvement could be attributed to the stimulant only.

I am indebted to Dr. F. M. Turner, medical superintendent of the hospital, for permission to publish the case.

A NEW METHOD FOR LOCALISING BRAIN LESIONS.



BY ROBERT H. COX, F.R.C.S. IREL.,
SURGEON TO THE IMPERIAL MARITIME CUSTOMS, CHINA.

THAT there is need for a more perfect method of locating the important areas of the cerebral cortex on the overlying surface of the scalp will, I think, be admitted by all, seeing that most of, if not all, the methods generally employed are either limited in their scope or complicated in their application, and many give rise to error by the use of a standard measure—the inch or the centimetre—for varying surfaces. The method which I am about to describe will, I think, be found devoid of these objections. For its use two things are necessary—viz., (*a*) an instrument which I have invented and called (for want of a better name) a cerebro-graphometer; and (*b*) a diagrammatic map of a hemisphere of the brain, prepared from readings made by the use of the same instrument on the cadaver and on casts of the brain *in situ*. This latter may, however, be replaced or augmented by a list of indices made in the same way.

[The author has prepared such a "list of indices," showing in much detail the correspondence between the letters and figures marked on the instrument and various regions of the brain—namely, motor centres (nine in number), sensory centres (hearing and sight), special convolutions (fourteen in number), special fissures (those of Rolando and Sylvius), the middle meningeal artery, and the cerebellum.]

The instrument itself consists entirely of the mechanical device known technically as "lazy tongs" formed into a circle with two accessory loops. The circle or base contains twenty-eight fenestræ and has attached to it

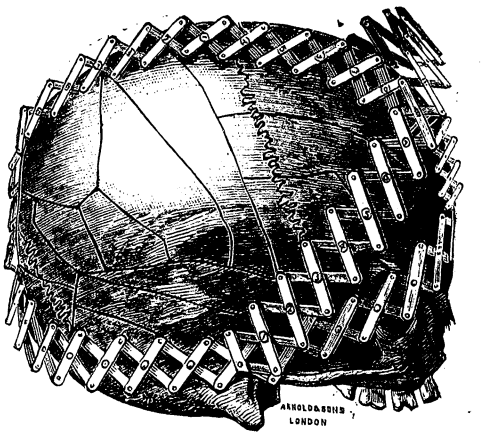


FIG. 1.

A diagrammatic map (on a gnomonic projection) of the external surface of a hemisphere of the brain, showing the boundaries of the lobes and convolutions and the lines of latitude and longitude corresponding to the engraved rivets of the instrument.

externally at four equi-distant parts the two accessory loops by their end rivets (excepting at one place, where the attachment is at the rivet third from the end) in such a way that the loops arch over the circle at right angles to each other, while at the same time they are capable of a hinge-like movement. One loop bears on its central rivets the numerals, beginning at each end with 1 and ending in the middle with 10; while the other loop has the letters A and V in consecutive order from before backwards, the rivet marked T being that connecting the loop with the circle behind. The map (Fig. 1) is made on a gnomonic projection with the radii, or longitudinal lines, marked by letters, and the semicircles, or lines of latitude, by numerals, both of which correspond with the engraved

FIG. 2.

The regions enumerated in Fig. 1 are here projected on the right side of the skull. The illustration also shows the instrument in position for localising.

loops of the instrument. Fig. 2 represents the instrument in position for localising.

To use the instrument it is necessary to extend it in all parts and apply it to the human head, with the rivet forming the junction of the lettered loop with the circle (below that marked "A") on the glabella and the rivet marked "V" (at the extreme end of the same band) to the occipital protuberance, when the loop between these two points should be pressed down to the skull in the middle line; while the circle is also closed on the skull on such a plane that the central rivet, marked 10, of the numbered loop shall lie on the middle line, as shown by the lettered loop. The instrument is thus fixed to the head by the circular band and the lettered loop, while the numbered loop is capable of moving backwards and forwards with a hinge-like motion, during which motion each numbered rivet describes a semicircle of latitude, and the portion of the same band from one of the fixed rivets to the numeral 10, as it extends to each letter, will give the radii of longitude. With the instrument thus in position, to find any given region—say, Broca's lobe—it is only necessary to consult either the map (Fig. 1) or the list of indices for the bearings there given, as $\frac{C}{4}$ (left side), when by moving the 10 of the numbered loop forward to "C" and pressing it down on the scalp the numeral "4" will lie over the part. Rolando's fissure may be found in a similar way by locating each end and joining the two points by a straight line. Localising by this method may be thus summed up: 1. Application of the apparatus. Extend the instrument and apply the end of the lettered loop marked "V" to the occipital protuberance and the other end to the glabella, then press down the loop to the scalp in the middle line. Close the circle round the head so that the 10 on the numbered loop will lie on the lettered loop. 2. Location of part sought for. Consult either the map or the list of indices for the bearings. Place the number 10 on the letter of longitude and press the numbered loop down, when the number of latitude will rest over the part sought for.

Having thus shown the simplicity of the method, for the carrying out of which no recourse need be had to the science of mathematics in any of its branches, and the almost automatic action of the cerebro-graphometer, I would now ask attention while I try to explain its accuracy. As may be seen at a glance, the instrument is equally applicable to all sized heads and forms its own unit of measurement for each, thus eliminating the errors due to the use of standard measure for a varying surface. The two fixed points taken are easily found and are those which have proved most reliable—the glabella and the occipital protuberance. The circular band is placed on that plane of

Hosted by Google

which Professor Fraser, in his "Guide to Operations on the Brain," has written: "And, finally, the keynote of all the remarks which are to follow is this, that for normal heads after birth the position of any structure of importance in their cavities varies proportionally with the variations of the circumference as given by the circumferential tapes of the respective heads." If this be true, or even approximately so, it points to this plane as the one most likely to afford the minimum amount of variation in the relative position of the cranial contents. Of course, as the markings of no two brains are the same, therefore no mechanical method can give perfect accuracy; but I hold that this method is the nearest approach yet to that goal, which, indeed, seemed to be reached with regard to Rolando's fissure in the only cases which I had an opportunity of testing it. That some of the bearings given may not prove to be the average when tested by others I am prepared to find, seeing that the material at my disposal has been very limited; but the investigation of those whose opportunities are greater would soon remedy this; yet in no case do I expect the average of others to vary from my own to such an extent as may not be included in the circle of an inch trephine. In conclusion, I would add that the cerebro-graphometer is compact, light, durable, and capable of being rendered aseptic by boiling. Messrs. Arnold and Sons, London, are the makers.

GUY'S HOSPITAL.

A CASE OF ACUTE HÆMORRHAGIC PANCREATITIS; FAT NECROSIS OF THE OMENTUM; LAPAROTOMY; NECROPSY.

(Under the care of Dr. L. A. PARRY, Mr. L. A. DUNN, and Dr. G. NEWTON PITT.)

A STOUT man aged sixty years was admitted on Aug. 25th, 1895, into the paying ward of Guy's Hospital under the care of the resident medical officer, Dr. L. A. Parry, for constipation and vomiting accompanied by abdominal pain. Thirty years previously he had had an attack of inflammation of the bowels, for which leeches had been applied to the surface of the abdomen, and a year before admission to hospital he had had an attack of rheumatic fever. On Aug. 18th he had a slight attack of abdominal pain, which soon passed away. On the 21st he was suddenly seized with acute pain in the epigastric region, which spread over the abdomen and was accompanied by sickness, the act of vomiting requiring some effort. Absolute constipation ensued; no fæces or flatus passed, but some fæces were removed with an enema. The abdomen became distended. Previously to this the bowels had been opened daily. He vomited throughout the 22nd and the 23rd, but when solid food was stopped and only liquid allowed in limited quantities the vomiting abated. The pain of which he had complained was readily held in check with morphia. On admission he was not at all collapsed; his pulse was 70 per minute, regular, and of rather high tension; the temperature was 99° F., and the tongue moist. The abdomen was uniformly, but not greatly, distended; there was no tumour or other abnormality to be detected either by percussion or palpation. There was a dull, aching pain over the abdomen, which was slightly tender on pressure. The rectum was empty and normal, no hernia could be detected, and the urine on examination was found to be normal. He vomited up small quantities of bile-stained fluid, free from any foul odour. Mr. Dunn, and afterwards Dr. Pitt, were called in consultation. A diagnosis of acute intestinal obstruction without strangulation was made. Internal strangulation was negatived by the absence of collapse, and the same reason, together with the absence of distension, excluded volvulus. None of the ordinary symptoms pointed to intussusception. Obstruction from an impacted gall-stone, inflammation in the upper part of the small intestine, and a complete, following upon a chronic, obstruction were discussed, but the history did not definitely indicate any of these. It was thought that the symptoms were not sufficiently urgent to require immediate laparotomy and that they might subside under treatment. He was ordered a pill containing a quarter of a grain of extractum belladonnæ every four hours. He was fed with nutrient enemata and his mouth was washed out frequently with acidulated water. A soap enema was administered and a small quantity of soft fæces of normal colour was brought away. This treatment was continued for eighteen hours. On the 26th he seemed much better, the sickness had ceased, the pulse-rate was 88, the temperature 100°, and forty ounces of urine had been passed, while the pain and distension had not increased. He was now allowed two drachms of peptonised milk every half hour; this was at once followed by vomiting of bile-stained fluid; small doses of soda-water produced the like result, so after twelve hours everything by the mouth—including the pills, which appeared to be causing slight delirium—was stopped. Soon the vomit consisted of intestinal contents and over a pint of foul bile-stained fluid was brought up. The abdomen became more distended and the patient complained of great weakness. On account of the increasing gravity of his condition it was felt that an exploratory operation should be no longer delayed. At 11 A.M. on the 27th Mr. Dunn performed a median laparotomy; coils of distended small intestine presented in the wound; the hernial rings, the appendix, and the gall-bladder were examined and found to the normal. The large intestine was collapsed, but no seat of obstruction could be found. The small intestine was opened and a Paul's tube tied to drain its contents. The operation lasted fifty minutes. Very little gas or fæces escaped by the tube. After some time he vomited up a quantity of foul intestinal contents and died at 3 P.M.

Necropsy.—A post-mortem inspection limited to the abdomen was made next day, where extensive decomposition had already taken place, precluding any bacteriological research. All the intestines, both large and small, were distended. The ileum had been opened six feet above the ileo-cæcal valve. Nothing abnormal was noticed until most of the intestines had been removed, when numerous small white and orange-coloured spots were noticed dotted over the mesocolon not far from the pancreas, but none elsewhere. The abdomen was free from peritonitis. The pancreas was found to be very large and indurated. On section this was found to be the result of infiltration with blood, which was already partially decolourised and was of some days' duration. The fat in the neighbourhood of the organ for a distance of two inches was dotted with areas of fat necrosis, many spots being stained of an orange colour; but the necrotic areas were not immediately contiguous to the pancreas, and at some distance from one another they were also discrete. The pancreas measured seven inches long, one and three-quarter inches vertically, and an inch and an eighth antero-posteriorly. When hardened the pancreas showed large necrotic areas, in which all the nuclei failed to stain, while the tissue was also infiltrated with blood. The adjacent portions of the pancreas appeared normal and practically free from any cell infiltration or evidence of irritation or inflammation. Calcareous salts appear to have deposited in the areas of necrotic fat.

Remarks by Dr. NEWTON PITT.—This case is an extremely instructive one and illustrates the great if not insuperable difficulty some of these cases present in diagnosis. The primary lesion appears to have been an acute necrosis of the pancreas with hæmorrhage. The symptoms presented by the patient, who had previously enjoyed good health and gave no history of any injury, were a passing attack of abdominal pain on Aug. 18th, and on the 21st an acute attack of abdominal pain with sickness and constipation. These continued for four days until he came under our observation. When admitted the pulse-rate was 70, there was no collapse or evidence of either peritonitis or intestinal strangulation. The symptoms appeared to point to intestinal obstruction, and at first, at any rate, the patient's condition did not appear to be one of urgent danger, and it was thought that the symptoms might subside if the stomach could obtain absolute rest. Had Mr. Dunn performed laparotomy at this early stage it is doubtful whether he would have

Hosted by Google

discovered anything abnormal, as the fat necrosis was limited in amount and was not observable even at the necropsy until most of the intestines had been removed. Under treatment the vomiting ceased for eighteen hours, but returned as soon as food was administered by the mouth, and although the patient was again fed for twelve hours by the rectum only, he rapidly became weaker, the pulse ran up to 88 and was very small, the temperature to 100°, and it was obvious that unless the condition was one that was relievable by operative means he would die.

Since Dr. Fitz's Middleton-Goldsmith Lectures on Acute Pancreatitis in 1889, when he collected fifty-four cases besides sixteen cases of extensive hæmorrhage in the region of the pancreas, several cases have been reported, and the lesion must be much more frequent than was previously supposed, as Dr. Thayer has within the last six years observed six cases on the post-mortem table and one at operation. The symptoms which Dr. Fitz found to be most characteristic of acute pancreatitis were sudden and severe epigastric pain without obvious cause, followed by tenderness, vomiting, slight pyrexia, flatulent distension of the abdomen, and complete constipation. These were all noted in the present case. Of the remaining symptoms which he considered characteristic—viz., collapse, prostration, feeble pulse, and the presence of a resonant area with deep-seated resistance lying between the umbilicus and epigastrium and evidences of deep-seated peritonitis—the two latter were never present, and the former only within the last few hours of life. Thayer in 1895 published what he considers to be the second case reported in literature in which a correct diagnosis of acute pancreatitis was made, and the first in which the diagnosis was followed by a successful operation. He also refers to three cases published by Körte, Atkinson, and Cutler, in which an ante-mortem diagnosis was made. The cases in brief are as follows. Thayer's patient was a man aged thirty-four years who had had three or four paroxysmal attacks of epigastric pain with some pyrexia; the presence of a tympanitic tumour in the region of the pancreas was noticed, which, when drained, proved to be a para-pancreatic abscess. Körte has operated upon two cases of hæmorrhagic suppurative pancreatitis, the first of which he diagnosed as an abscess of the pancreas, which he drained, the man dying eight days later. He was aged thirty-seven years, and his illness commenced with sudden severe abdominal pain. The second case was that of a woman who had complained of sudden severe abdominal pain with increased abdominal resistance in the region of the umbilicus. An internal strangulation was diagnosed. When laparotomy was performed a pancreatic abscess was found, which was drained, and the woman survived for twenty-eight days. Atkinson reports the case of a woman aged thirty-five years with a history of attacks of hepatic colic for fifteen months. When seen she had been worse for nine weeks; her urine contained a trace of sugar and there was some pyrexia. She had diarrhœa and vomiting and a tumour above the umbilicus three and a half inches across. The diagnosis was a stone in the common duct with a pancreatic abscess. She died after twelve weeks. Cutler reports a case of a stone impacted in the common duct and hæmorrhage around the pancreas. Fat necrosis was also found with blood-stained fluid in the peritoneum.

In considering the difficulties of diagnosis the group in which there is a tumour in the region of the pancreas, form a comparatively easy group, which, now that attention has been drawn to their occurrence, should generally be capable of accurate diagnosis. A second group is that in which there is evidence of a stone impacted in the common duct, and a third where there is a definite history of abdominal injury, probably affecting the pancreas. Cases which do not fall within any of these groups can but very rarely be diagnosed, as the symptoms are suggestive but not distinctive. The cases of successful diagnosis which have been published belong to one or other of the above groups, with but two or three exceptions. Yet none of the writers have drawn attention to this. In the present instance pancreatitis ought to have been one of the conditions borne in mind, but a positive diagnosis would not have been justified; this uncertainty is also illustrated by the two following cases which have occurred within the past year with practically identical symptoms. The first was a woman aged fifty-eight years, who was seized with sudden abdominal pain, which came and went in paroxysms, abdominal tenderness, vomiting which at first increased in severity, but was relieved when all food by the mouth was stopped, constipation after the first day, a pulse of 100, and subnormal temperature. For some days the patient's condition did not appear to be one of great gravity as there was no collapse and the pulse remained fair; but upon laparotomy a gall-stone was found, as was suspected, obstructing the ileum and was removed. The second case was that of a man aged forty-nine years, who was about to leave the hospital convalescent from an attack of abdominal colic when the pain returned severely and was accompanied by tenderness, vomiting, and complete constipation. The temperature varied from 100° to 103° F. He became very prostrate, collapsed, and his pulse was 114. There was a markedly increased resistance and tenderness in the abdomen above the umbilicus. He died at the end of six days, when an acute membranous enteritis was found involving some six feet of the jejunum and ileum. The symptoms in all three cases were very similar, but in none would a positive diagnosis have been justified. The causation of these cases of acute pancreatitis has yet to be determined. Possibly, as has been pointed out, the process may be an acute infective one similar to that affecting the parotid in mumps, or it may be an inflammatory process spreading to the duct from the gastro-duodenitis. Some cases are undoubtedly due to traumatism and others to secondary changes ensuing on impaction of a calculus in the duct. With regard to the fat necrosis which is so commonly associated with the pancreatic disease, the affected areas are generally irregularly distributed, and it is probable that in many cases, and almost certain in most of those associated with traumatism, that it is due to contact with extravasated pancreatic secretion. The view that the necrosis is the result of a trophic nerve influence remains unconfirmed by further experience.

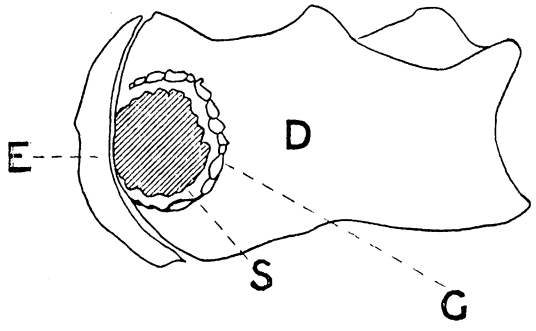
HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A CASE OF NECROSIS OF THE OS CALCIS IN A CHILD; OPERATION.

(Under the care of Mr. EDMUND OWEN.)



For the notes of this case we are indebted to Mr. G. Templeton, surgical registrar to the hospital.

A boy seven and a half years of age, the son of a labourer, was admitted to the Louise Ward of the Children's Hospital on Nov. 19th, 1896. His mother said that he had "rheumatic fever" in December, 1895, but he had had no other illness. After this so-called rheumatic fever—which was in all probability a severe attack of pyæmic necrosis—an abscess formed over the back of the lower end of the left ulna, and for fourteen weeks subsequently the child was an in-patient at a country hospital. He was a delicate-looking boy. The right leg was swollen and unhealthy and along the inner aspect there were seven sinuses leading down to the tibial diaphysis, which seemed to be necrosed throughout. This was surrounded by an involucrum of new bone which had given way a little above the middle of the leg. Another sinus existed over the inner side of the right os calcis, through which a probe could be passed to the bare bone. The lower third of the left tibial diaphysis was also necrosed and was surrounded by an involucrum through which two sinuses extended and the lower third of the left ulna could be made out to be necrosed by examining through two sinuses which led down to it. Under chloroform Mr. Owen removed the sequestra from the tibiæ, whilst Mr. Templeton operated in a similar manner upon the ulna. Mr. Owen then enlarged the sinus over the os calcis, and having gouged away some of the surrounding bone extracted a sequestrum of the size of a pea from the interior. The boy's general condition greatly improved after this, all the wounds filling up with healthy granulation tissue, but at the date of the last note (Dec. 3rd, 1896) he was still in hospital.

Remarks by Mr. OWEN.—The case is an ordinary one of acute septic osteo-myelitis, beginning, as is usually the case, at the end of a diaphysis and ending in necrosis. The feature, however, to which I desire to draw particular attention is the necrosis in the os calcis. The association of this necrosis with a similar condition in several of the other

Hosted by Google

diaphyses suffices to indicate its pathology; but when an os calcis is affected by itself the actual state of affairs may not be so readily understood. Throughout childhood the os calcis consists of a diaphysis of spongy bone, with a cartilaginous epiphysis at the posterior surface. At the tenth year this—the epiphysis—begins to ossify, and it becomes fused with the rest of the bone just after puberty. From time immemorial the hinder end of the heel has been peculiarly vulnerable, and if a boy happen to have it struck or otherwise hurt the vitality of the delicate bone-tissue recently deposited at the growing end of the diaphysis—that is, immediately anterior to the junction-cartilage—is lowered. And if it so happen that at this time there are staphylococci circulating in the child's blood they will probably seize upon that tissue, determine a localised Haversian thrombosis in it, and an almost inevitable

Necrosis of os calcis. D, Diaphysis of os calcis. E, Epiphysis. G, Wall of granulation tissue lining cavity. S, Sequestrum.

necrosis. The heel then becomes extremely tender and in a short while the skin over it is found to be red and hot; after a time the acute symptoms subside. The presence of the dead portion of the diaphysis determines a growth of granulation tissue in the surrounding bone, and in due course the pea-like sequestrum is detached by it and then lies loose in a suppurating cavity which is walled in with granulations. If the case be allowed to drift on nature will have to arrange for the extrusion of the sequestrum, which she generally does by forming an abscess on the inner or outer side of the calcaneum. But sometimes she is not so skilful in her operation, but by clearing an upward track for the evacuation she involves the posterior astragalo-calcanean joint in septic inflammation, the destructive process extending thence into the ankle-joint itself. I have had to perform Syme's amputation in such a case and have subsequently been able to trace out the pathological sequence of events described above with the utmost clearness. For clinical purposes the os calcis must be regarded as one of the long bones, with a shaft and a single epiphysis like the clavicle. The delicate tissue at the growing end of the diaphysis is very apt to become, especially after injury, the area of cultivation of staphylococci, which determine septic thrombosis and necrosis. Persistent deep-seated tenderness in the os calcis of a child, with, perhaps, swelling and œdema or redness about the heel, should suggest exploration. For if art does not come to the assistance of nature it is possible that the septic disease may extend into or around the astragalus and wreck the ankle-joint.

RADCLIFFE INFIRMARY, OXFORD.

A CASE OF COMPOUND FRACTURE OF THE ROOF OF THE ORBIT; TREPHINING; RECOVERY.

(Under the care of Mr. A. WINKFIELD.)

RECOVERY after punctured wounds of the base of the skull with cerebral injury inflicted through the orbit is so rarely seen, even at the present day, that we are pleased to bring before the notice of our readers the account of one which is an exception to the rule. The reason for this fatality was well put by the late Mr. Hulke[1]: "In no class of cases is the surgeon more likely to be put off his guard as to the exact nature and extent of the injury. At first all that may be apparent is the slight injury of the external parts—a trifling wound of the upper lid, and sometimes not even this, for the instrument may have slipped under the lid and left merely a patch of ecchymosis in the conjunctiva. Brain symptoms there may be none. Two or three days may pass over, during which the patient goes about as usual; then brain symptoms make their appearance, sometimes suddenly, and the patient dies in the course of a few hours or days and the true nature of the case is revealed only in the post-mortem room." This class of injury combines the dangers of a punctured wound with the introduction of foreign bodies and septic material and the dangers of a wound of the brain substance. There is no doubt that it is not the wound of the brain alone, for wounds of the frontal lobes are less dangerous than those of other parts of the brain, and injuries resulting from the lodgement of a gun breech in the orbit and brain injury are less fatal than punctured wounds from sticks or umbrellas, which cause far less injury to the brain. These cases must be treated on the same principles that guide us in the treatment of punctured fractures in other parts of the skull. The wound must be thoroughly examined for foreign bodies (surgical literature contains too many examples of inefficient search), thoroughly cleansed, and provision made for thorough drainage. The importance of these remarks will be apparent when we remind our readers that when investigating this subject some years ago we found that seventeen out of eighteen persons suffering from this kind of injury died. Yet there are recorded cases in which recovery resulted ultimately; two of these are quoted by Sir Prescott Hewitt[2] in his lectures on injuries to the head, whilst others were under the care of Beaumont,[3] Hulke,[4] Laplace,[5] Godlee and Pope,[6] A. F. Hawkins,[7] and Palaillon.[8] We are indebted for the report of this case to Dr. W. L. Fry, house surgeon.

A boy aged twelve years was admitted on the afternoon of Sept. 14th, 1896, with a history that whilst running with a short joint of fishing-rod in his hand he had fallen on the ferrule end, which had penetrated his eye. Upon examination a ragged punctured wound about half an inch in length through the inner part of the right upper eyelid was found. A probe passed some inches through the wound in a backward direction and fragments of bone could be felt and brain matter was seen in the wound; the conjunctiva was bruised and the eyelids were swollen. Under chloroform Mr. Winkfield examined the wound, and with the little finger a fracture could be felt in the roof of the orbit extending far backwards, but no foreign body or depressed or loose bone could be detected; brain matter was escaping freely through the wound, which was cleansed and bound up. On the next day the swelling of the eyelids had increased; the boy's condition was fairly good, but with some twitchings of the left arm. On the 16th the temperature was 100° F.; there was some sanguineous discharge from the wound. Urine was passed involuntarily; the boy was drowsy, but answered questions rationally. On the 17th the temperature was 100°. There were twitchings of both arms and a good deal of restlessness at times. On the 18th the boy's condition was not improving and the discharge from the wound was becoming offensive. Mr. Winkfield trephined with a large-sized trephine just above the supra-orbital margin and enlarged the opening in the bone with cutting forceps. The dura mater projected tensely when the disc of bone was removed. A finger was introduced through the opening and passed along the upper surface of the orbital plate of the frontal bone and detected the fissure fracture, its edges being a little uneven, but no foreign body or depressed bone could be felt; some fœtid fluid escaped when the finger was withdrawn. The dura mater was punctured with a small knife and some fœtid matter escaped. A drainage-tube was introduced through the trephine opening and the disc of bone replaced. Another drainage-tube was passed through the wound in the eyelid. The temperature, which was 102° before the operation, dropped to 99° and remained normal for several days. The tubes were frequently removed and cleansed, and a free discharge took place of clear fluid resembling cerebro-spinal fluid. Shortly after the operation a large crop of herpes appeared symmetrically on

Hosted by Google

both upper arms, the boy got very thin, and some boils appeared upon his back which were opened freely under an anæsthetic. On the 29th he had a rigor, with a temperature of 103°, and he became very ill for a week, complaining of headache, which was relieved by the flow of fluid, he grew noisy and restless, resisted all interference, and became very emaciated. There was great difficulty in feeding him. When the tubes were taken out the fluid continued to flow at intervals, and when the wound was closing a copious discharge of similar fluid came from the nose; he would raise himself upon his pillows and allow the fluid to pour from his nose in a stream. As the fluid escaped the head symptoms were relieved, and when the flow from the nose ceased the scabs over the frontal wound would break down and the flow began then again. The temperature remained slightly above normal until Oct. 13th, when it rose to 103°, with symptoms of recrudescence of the meningeal trouble. The attack lasted three days and then quieted down. The discharge gradually ceased, the boy became bright in himself although very fretful, and he could not recall what had happened the previous day, but he could answer questions with intelligence. After Oct. 18th the temperature remained normal; the boy is able to walk alone, and has laid on flesh, and can read with enjoyment. His temper, which was very irritable, is now quite good and he has a fair memory. There are still granulations over the frontal wound and a piece of bare bone can be felt with a probe. This is probably a portion of the bone replaced after the trephining.

On Dec. 12th the opening was enlarged and this disc of dead bone removed, after which the wound healed kindly.

Medical Societies.

EPIDEMIOLOGICAL SOCIETY.

The Spread of the Plague.

A MEETING of this society was held on Dec. 18th, 1896, the President, Professor LANE NOTTER, being in the chair.

Dr. CANTLIE addressed the society on the Spread of the Plague. We publish the beginning of his lecture in our present issue.

Dr. LOWSON said that his experience of plague extended to over 5000 cases. He had made many observations and never found plague bacilli in the soil, although a smaller dumb-bell shaped bacillus was almost invariably present and had, he thought, been mistaken for it by other observers. He admitted that the upper layers of the soil might ultimately become infected by dejecta. He thought that dissemination by fomites was of great importance, but this dissemination did not seem to take place over long distances. At the close of winter the Chinese pawned or sold their warm garments, and they also sold the clothes of those who died from the plague without any previous disinfection. These customs had a great influence in spreading the infection. Carriage through the air was of slight importance. The infection usually spread slowly and along trade routes. He believed the popular idea that an epidemic among rats preceded each epidemic among men was unfounded. Both men and rats were affected simultaneously, but the disease ran a more rapid course in rats, and hence the epidemic would spread more quickly among them. Pigs were liable to plague, typical bacilli being found. He had been unable to communicate it to pigeons or hens. When calves were inoculated there was a reaction, the temperature rising to 103° F., but no bacilli were found in the blood. The serum of animals so treated appeared to have some prophylactic effect on rabbits. There had been some striking differences between the course of the disease in 1894 and 1896. In 1894 buboes were chiefly in the groin. Convulsions, intermittent pulse, and heart failure were common. In 1896 the glandular enlargements were chiefly abdominal, and nephritis was a frequent complication, while nervous and cardiac symptoms were rare. He thought the recent outbreak at Bombay had come by trade routes, probably from Singapore. There was an epidemic raging at Merv which might possibly be plague, and the disease might have come by that route. The mortality was lowest among western-born persons (18 per cent.), while the mortality of Eurasians was as great as that of the Chinese (80 per cent.). There was little spread except by direct contagion from the patient or from the dust and dirt of the room. The soldiers who volunteered for sanitary duty from the Shropshire regiment were not attacked after it was the practice to disinfect the soil thoroughly before it was cleared out from the houses. He thought that direct inoculation through abrasions was common in 1894, but escaped notice because pure cultures give rise to no inflammatory reaction at the site of inoculation.

Dr. PAYNE said that the description of these recent epidemics corresponded closely with those in Europe in former centuries. It had always been held that a persistent high temperature had the effect of stopping an epidemic. He thought the practical immunity of India was accounted for by the fact that the iso-thermal line of 78°, which involved the plague districts of China, only just touched the north of India. He agreed with what had been said about pestis minor, and considered that there was much evidence of such a modified form of plague in Astrakhan and Mesopotamia. He deprecated the suggestion of giving a new name to the disease.

Dr. MANSON said it must be remembered that non-venereal buboes were very common in the East. Buboes were also common in the "river fever" of Japan, which might possibly turn out to be pestis minor. He thought that cases where the disease appeared on board ship long after leaving an infected port might be due to infection from clothes which had been unpacked in the course of the journey.

Dr. WASHBOURN remarked on the resemblance of plague bacilli to those of various forms of septicæmia in animals. The mode of infection might vary just as in the case of anthrax, being sometimes inoculated by way of the skin, sometimes inspired, and sometimes taken with the food.

Professor CAYLEY (Netley) thought that the absence of the spread of plague in India was due to the cleanly habits of the natives, at any rate in country districts.

Dr. K. MACLEOD doubted if plague even in a modified form was ever present in Calcutta.

Dr. CLEMÓW (Cronstadt) said that the epidemic which was mentioned as raging at Merv had decimated the population, but so far as he could gather it was a malignant form of malaria and not plague.

Dr. CANTLIE, in reply, agreed with Dr. Lowson as to the change in type of the second epidemic. He thought there was no doubt about the existence of mild cases, running an atypical course, in which bacilli indistinguishable from those of plague could be demonstrated.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—Hysterectomy.

A MEETING of this society was held on Dec. 10th, Dr. CLEMENT GODSON, President, being in the chair.

Mr. E. TENISON COLLINS (Cardiff) showed a specimen of Strangulated Ovarian Cyst, and read notes of the case.

Dr. G. ELDER (Nottingham) showed three specimens of Pyosalpinx.

Dr. PURCELL, Dr. ELDER, and Dr. EDGE showed specimens illustrating their papers on Hysterectomy.

Three papers were read on the subject of Hysterectomy:—(1) Fibro-myoma Removed by Pan-Hysterectomy, with a Review of Different Methods, by F. A. PURCELL, M.D.R.U.I.; (2) Remarks Suggested by Four Recent Cases of Hysterectomy, by G. ELDER, M.D. Glasg.; and (3) Fibro-myomatous Uterus Removed by Doyen's Method of Abdominal Pan-Hysterectomy, by F. EDGE M.D. Lond., F.R C.S. Eng.—In the discussion that followed Mr. MAYO ROBSON (Leeds) said that he was much interested in the subject of shock, referred to by Dr. Elder. Some time ago he read a paper on the Treatment of Shock by Transfusion before the Clinical Society. He was led to adopt this treatment by the resemblance between death from shock and death from hæmorrhage which had been pointed out by Dr. Lauder Brunton. In shock the blood was not actually lost, but it was lost to the circulation owing to its collecting in the abdominal vessels. If this stagnant blood could be set circulating again the patient might recover and transfusion had that effect. It was sometimes necessary to transfuse a second and even a third time, for there might be recurrence of shock just as there might be recurrence of hæmorrhage. He had often been disappointed with the

Hosted by Google

microscope in diagnosis and he preferred to rely on clinical signs. No microscopist could tell with certainty whether a case were one of fungous endometritis or of malignant disease. The subject of hysterectomy was always interesting, for they were getting nearer to a perfected operation. Jessett's, Lebec's, and Doyen's methods were all the same in principle though worked out independently, and some such procedure would come to be the recognised operation. For his own part he had mostly adopted the intra-peritoneal method, based on Schroeder's, with this modification, that after suturing the peritoneal flaps he brought the stump up to the abdominal wound, fixing the parietal peritoneum round it, and the aponeurotic structures over it. By this means the uterine cicatrix was extra-peritoneal, and there was no chance of adhesions between intestine and stump such as might lead to intestinal obstruction. The only patient he had lost died on the fourteenth day from intestinal obstruction. He had no doubt that the method of the future would be one of the three above mentioned.—Mr. BOWREMAN JESSETT believed that a question of great importance in the future would be the early treatment of myoma by operation. At present patients were told to wait for the menopause; no doubt at this time a few myomata disappeared, but many were not affected. Early removal could be accomplished with safety, but in later stages it was often difficult and dangerous. The most difficult case he had had was a recent one, where the tumour weighed 24 lb. There were universal adhesions. The patient died from shock. Had the operation been performed some years earlier her life might have been spared. This case was very like the second one of Dr. Elder. The shock was largely due to the removal of a large mass of tissue, but perhaps even more to the separation of intestinal adhesions. He had been much impressed by Mr. Mayo Robson's remarks on the subject of shock and its treatment by transfusion and thought they would all do well to bear them in mind. He believed that before long total extirpation would become the recognised method of dealing with myoma of the uterus; the shock was much less, and in this respect the case closely resembled one of vaginal hysterectomy. Doyen's and Lebec's operations were practically the same as his own, but he believed that all three were worked out independently, well illustrating the tendency of operators in different parts of the world. He had sometimes sent down scrapings for examination from cases where the clinical features pointed to a benign condition, and the report had been that they indicated malignant disease. But he had trusted the clinical signs and found that they went on well. There was the difficulty that the part curetted might not be the diseased part because the scraping did not go deep enough. He noted that Dr. Elder in his vaginal hysterectomies left the appendages behind. He thought that in younger women it was usually better not to remove them, for otherwise the patient was subject to much pain and discomfort at the monthly periods for some time after.—Dr. HEYWOOD SMITH, referring to Mr. Mayo Robson's remarks, said he thought it was generally better in intra-peritoneal cases to leave the stump free in the pelvis, for by this means tension was lessened; and, moreover, he believed that when adhesions occurred the site was usually the place where the ovarian vessels were tied. In spite of the success of pan-hysterectomy he believed that a perfected intra-peritoneal method would give even better results, because it was most important to shorten the duration of the operation. He thought that in young women it was better to leave the ovaries and tubes, if healthy, even if the patient suffered some temporary discomfort with the molimina, because, as Dr. Routh had maintained in a paper read before the society, the ovaries seemed to exert a special action independent of the function of ovulation.—Dr. HERBERT SNOW said that microscopic examination was a fetich to many men. As a matter of fact, clinical data were far more reliable. Many errors were possible, even if a large piece of tissue were available. The microscope could prove a positive but not a negative condition.—Dr. BALDWIN (of Ohio, U.S.A.) said that he had read a paper on Hysterectomy at the last meeting of the Ohio State Medical Society, describing what to many was a new procedure, and based on over fifty cases. He proceeded as follows: After opening the abdomen the most accessible broad ligament was clamped outside the ovary down to the uterus. A short clamp was placed on the ovarian artery close to the uterus. Then with a single cut of the scalpel the broad ligament was divided within the first clamp. The procedure was repeated on the opposite side. Peritoneal flaps were then made, front and back, in the usual way. The uterine artery on each side was seized with forceps and the uterus amputated just above the internal os in a wedge fashion, so as to give two uterine flaps. Each uterine artery was then tied, without including any tissue besides in the ligature. The ovarian artery was drawn out, and similarly tied alone. Occasionally an aberrant vessel would bleed and also require ligature. A piece of gauze was passed down through the cervix into the vagina and left for drainage. The cervical flaps were then brought together after bringing down the round ligaments between them; the peritoneal surfaces were turned in and sutured over. The round ligaments held up the uterus and two new ligaments were formed by the folding in of the peritoneum. When there had been much dissection required or separation of adhesions he drained through the vagina or removed the cervix and passed iodoform gauze into the vagina. Notwithstanding antiseptic precautions he always felt safer if the vagina and peritoneal cavity were separate; and for this reason he generally left the stump formed by the cervix. By attention to the above details the risk of subsequent intestinal obstruction was minimised. He was much pleased to hear Mr. Jessett's remarks as to the early treatment of fibroid tumours. Formerly patients with ovarian cysts were often left till they were moribund before being operated upon; and similarly the practice with fibroids was generally to wait till bad symptoms developed. But the tendency was now certainly to operate earlier. As regards vaginal hysterectomy, they were by no means satisfied in America with the after results—there was too much recurrence. They were, therefore, beginning to adopt a combined vaginal and abdominal operation and to remove the whole of the broad ligaments. At the Johns Hopkins Hospital they were doing even more; they were dividing the pelvic peritoneum posteriorly, and removing the sacral glands. But this, he thought, was carrying operative zeal too far. If the disease were so advanced as to require this treatment it was too advanced, in his opinion, to be touched at all. By the combined method he had so far had no recurrence, but as it was not yet three years since he began it it was too soon to form conclusions. By the ordinary vaginal procedure it was impossible to get beyond the gross disease.—The PRESIDENT observed that he could quite corroborate what had been said by Mr. Mayo Robson, Mr. Jessett, Dr. Snow, and Dr. Baldwin as to the unreliable character of the evidence concerning malignancy supplied by microscopic examination.—Dr. ELDER, Dr. PURCELL, and Dr. EDGE briefly and suitably replied.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Dec. 10th, 1896, the President, Mr. WILLIAMSON, being in the chair.

Dr. G. MURRAY showed a case of Locomotor Ataxia with Charcot's Joint. The patient was a man thirty-three years of age, whose illness commenced three years ago with weakness in the knees and lightning pains in the legs. He had now marked ataxia and double optic atrophy. His right hip was swollen and there was a tense, elastic swelling in the joint, with marked grating on movement. The leg was shortened by two inches and a dislocation could be readily produced.

Dr. G. MURRAY showed a Case of Tetany in a child thirteen months old, with characteristic flexure at the metacarpo-phalangeal joints, the flexed elbows, and the adducted thumbs of tetany. The condition exactly resembled that produced in the monkey by the removal of the thyroid. The child improved by taking thyroid gland.

Mr. PAGE showed a girl seven years of age and a specimen of a tumour successfully removed from her lower jaw. The tumour was a central sarcoma (noticed for eight months) which had grown rapidly and was causing great deformity.

Mr. PAGE showed a woman and a Four Months' Fœtus and Placenta removed from her abdomen. She was the mother

Hosted by Google

of two children, the last being born in 1891. Menstruation had always been irregular since the birth of her first child, so that no diagnostic importance could be attributed to it. A fortnight before her admission to the infirmary she was seized with severe abdominal pain and vomiting. She did not know that she was pregnant. Since the attack of pain there had been a dark hæmorrhagic vaginal discharge. A cystic tumour was felt in the left of the pelvis separate from the uterus. On opening the abdomen a dark-coloured swelling came into view, with a hole in it plugged by clots; there was no blood free in the abdominal cavity. The swelling contained a good deal of fluid and clotted blood along with the specimen exhibited. She made a straightforward recovery.

Mr. PAGE also showed a man fifty-eight years of age who was seized with a sudden severe pain in his abdomen in April of last year. On this occasion he had a frequent desire to micturate, but could pass very little urine. Soon after he had a second attack of pain, which passed off in a few hours. Early in September a swelling was noticed in the epigastric and left hypochondriac region. It steadily increased and he became thinner and had constant pain. On admission to the infirmary a rounded, elastic, smooth swelling could be seen and felt on the left side of his upper abdomen. The abdomen was opened in the left linea semilunaris and a dark-coloured tumour was exposed. It could not be delivered and was incised *in situ*. A considerable quantity of laminated clot such as is found in an aneurysm was turned out of it and no fresh hæmorrhage occurred. The tumour was now seen to be in the lesser peritoneal sac. The opening in it was stitched to the parietes and the cavity plugged with gauze. The fluid removed was tested, but had none of the properties of pancreatic fluid. The patient had much improved in condition and the wound was now superficial. The most probable cause was rupture of a varicose vein.

Dr. CLAY showed a man who after being tapped five times for a purulent pleural effusion had his chest incised and drained. He was sent home cured five months previously, and had returned with all the signs of an extensive pleural effusion on the same (the left) side. On tapping him the fluid was found to be the ordinary clear effusion of simple pleurisy.

The PRESIDENT showed a child who was admitted to the infirmary with a Suppurating Tuberculous Knee. The operation consisted in dissecting out the whole of the diseased structures. The wound had only been dressed once again at the end of six weeks, when it was found to be entirely healed.

Dr. LIMONT showed a middle-aged man who fell from a scaffold three and a half years ago and gave his chest a severe wrench. He then noticed a swelling over the sternum which had gradually increased in size since. Except for some pain in it when at work he has had no symptoms. A large swelling was visible under the upper part of the sternum and the left second, third, and fourth costal cartilages. The skin over it was unaltered and there were no dilated veins. The tumour felt solid and appeared to be slightly moveable. It had eroded the sternum. There was no pulsation in it and no murmur was present. The heart sounds and breath sounds were normal. There were no previous symptoms. Was it an aneurysm filled with clot or a new growth in the mediastinum?

Mr. RUTHERFORD MORISON showed a young man on whom he had recently operated for a Calculus in the Pelvis of the Right Kidney. The incision scar was T-shaped, the vertical portion in the linea semilunaris, the transverse running back into the ilio-costal space as far as the edge of the quadratus lumborum. This was the incision he had introduced for all kidney operations some years ago and still advocated. The advantages of it were that the patient could lie on his back during operation, making anæsthesia easier; that the diagnosis in cases of tumour was verified when the abdomen was opened in the linea semilunaris and a mistake could then be more thoroughly compensated for; that the opposite kidney could be ascertained to be present and fairly normal before the diseased one was removed—a very essential precaution; that better access to the kidney was obtained by this than by any other incision; and that dependant drainage could be secured by this, but not by the abdominal incision alone.

A number of pathological specimens were exhibited by Dr. JAS. MURPHY, Mr. W. MARTIN, Mr. RUTHERFORD MORISON, and Mr. PAGE.

Reviews and Notices of Books.

Diseases of the Eye and Ophthalmoscopy, a Handbook for Physicians and Students. By Dr. A. EUGEN FICK, University of Zürich. Authorised translation by ALBERT B. HALE, A.B., M.D., one of the Ophthalmic Surgeons to the United Hebrew Charities, with a Glossary and 158 Illustrations, many of which are printed in colours. London: H. Kimpton. 1896. Pp. 488. Price 21*s.* net.

THE volume before us has been written by the author because he is of opinion that the best text-books of ophthalmology are too exhaustive, and he has endeavoured to supply the student with a compact treatise in which pathological statements and hypotheses as well as authorities should be referred to only so far as they may be necessary to illustrate diseased conditions and which might prove supplementary and complementary to the clinical study of diseases. The translation we may say at once is creditable to Dr. Hale of Chicago. It reads easily and is as a rule satisfactory, though sometimes needlessly hard words are used, as "diagnosticated" for diagnosed and "ectropionising" for everting, whilst a more elegant rendering of the original might have been given than is contained in the following sentence. Speaking of inflammation of the lacrymal sac the translation given is: "I cannot now discuss the treatment of the nasal mucous membrane; that of the tear sac must first attempt to secure a free passage into the nose, and, second, to restore the mucous membrane to its normal condition." Again, it is hardly correct to say that "a catarrh or a blennorrhœa is due to occlusion of the lacrymal passage into the nose."

The treatise is divided into two parts, the first dealing with the methods of examination, including the means of determining the acuteness of vision and errors of refraction, the sense of light and of colour, the field of vision, and the tests for binocular vision and for strabismus, and giving also an account of the objective methods of examination, such as keratoscopy, oblique illumination, and the use of the ophthalmoscope. The second part is devoted to the diseases of the eye, which are considered in the usual topographical order, each being preceded by a short account of the histology of the part. The observations made by the author are, as a rule, those of an unprejudiced mind, and although they might in some instances have been extended with advantage, yet they are sufficiently intelligible. He calls attention to the treatment of trachoma suggested by Keining, which consists in a firm massage applied to the exposed conjunctiva of the upper lid with a wad of cotton soaked in a solution containing 1 in 2000 of sublimate, but prefers himself massage with iodoform, which does not leave behind the grey coating that may on the following day lead to the postponement of the treatment. Iodoform massage is also less painful. In determining the degree of tension that an eye presents the author speaks in high terms of commendation of his namesake's, A. Fick's, tonometer, but it requires in use an amount of precaution and care that will render its introduction into practice, however trustworthy the results obtained may be, more than doubtful. The fingers are probably still the best tonometer. The dioptrics of the eye and the theory of the ophthalmoscope are fully entered into, and are illustrated by numerous diagrams, some of which are rendered more intelligible by being coloured. For the determination of astigmatism he gives the perference to the shadow test over other methods.

The observations on the lacrymal apparatus are sufficiently sensible. He slits up the canaliculus in cases of constriction of the canaliculi or mal-position of the puncta, and in cases of suppuration of the sac and nasal duct of a chronic character uses a solution of chloride of zinc of the strength

Hosted by Google

of 10 per cent. He admits, however, that precautions must be taken and that the reaction is very intense. The difficulty of limiting the effects of the remedy seems to be the chief objection to its employment.

In regard to cataract extraction he has always operated with iridectomy and intends to confine himself to that method. The details of the precautions he takes to avoid infection are to be commended. We have arrived at the conclusion that sport in the form of shooting is not pursued by the inhabitants of Chicago, for in the course of a very good chapter on Wounds of the Globe and Orbit, as well as in sections devoted to Wounds of the Cornea, Choroid, and Conjunctiva, scarcely a word is said in regard to gunshot wounds, although these have some special features of their own that deserve comment. As a working man we should like to have Dr. Fick, in the event of injury occasioning slight damage to the eye, on the jury empanelled to award damages. He considers that if the injured person "suffers a loss of 30 per cent. of his working power, and has, therefore, been injured 30 per cent. in his wage-earning capacity, there should be paid him for the remainder of his life 30 per cent. of his wages (income) as compensation." This is preposterous. A very slight injury may impair a man's power to perform certain kinds of work—for example, the cutting of intaglios of superior quality; but it would be, in our opinion, extremely unfair to burden the unfortunate man who has inflicted a slight injury on one eye of such a worker with a charge of 30 per cent. of his previous income for the rest of his life. The natural changes of advancing age prevent any man doing his best work in old age, and other branches of work can be taken up and excelled in, and the opposite eye can be exercised. Suppose a man to be earning £3 a week as a skilled cutter. He receives at thirty-five years of age a slight blow, impairing the transparency of the cornea or his power of accommodation. He expects to live to seventy. Is he to have £1820 or its equivalent given to him? The fact is, no such hard-and-fast rule can be laid down. Circumstances must be taken into account in all such accidents. The subject, which is not often mentioned in ophthalmic treatises, is one of importance and is here well discussed. The problem is mathematically presented by the following formula: $E = V\sqrt{G} \times \sqrt[4]{B} \times \sqrt[x]{K}$, when E signifies the earning capacity, V is the visual acuity, G the visual field, B the excursional field, and K the competitive element—that is, the capacity for obtaining a situation in the labour market. In the appendix there is a curious table for converting metric weights into troy weights, which seems quite out of place in a work on ophthalmology. A table on the relative value of English and metric measures for lenses would have been more serviceable. There is also a glossary of terms used in ophthalmology, with their etymology, which, however, is very incomplete.

As a whole the book is a valuable one and represents truthfully and well the present state of ophthalmic science and practice.

Surgical Diseases of the Ovaries and Fallopian Tubes, including Tubal Pregnancy. By J. BLAND SUTTON, F.R.C.S. Eng., Assistant Surgeon to the Middlesex Hospital, &c. With 146 Illustrations. New and Enlarged Edition. London, Paris, and Melbourne: Cassell and Company, Limited. 1896. Price 21*s*.

MR. BLAND SUTTON has taken advantage of the demand for a new edition of his work on the Surgical Diseases of the Ovaries and Fallopian Tubes to make several alterations, most of which are improvements, among which may be mentioned the addition of a new section on the Diseases of the Pelvic Peritoneum, and a considerable increase in the number of illustrations. As an example of the well-known principle that second thoughts are not always best, we may quote a sentence from the first edition. "*Microscopically examined*, menstrual fluid consists of blood-corpuscles and epithelial cells." In the edition before us this reads: "Menstrual *fluid* consists of blood-corpuscles and epithelium furnished by the mucous membrane of the uterus and vagina." The italics are ours. There are some practical points in the chapter on Irrigation and Drainage as to which other authorities hold somewhat different views from those here expressed. Thus in cases where a drainage-tube is used it is mentioned as a proper procedure that the fluid should be sucked up from it by means of a syringe. It is considered much better practice by many operators to simply empty the drainage-tube with a piece of glass tubing without any suction, which increases the chance of omentum getting into the drainage-tube. Nor do we see in this chapter any mention of the use of iodoform gauze instead of a drainage-tube.

The author seems to us, as might have been anticipated, to be at his best in Part III., which deals with Tubal Pregnancy. The book undoubtedly ranks as one of the best among the standard works on this subject.

Physiologie des Menschen und der Säugethiere. Lehrbuch für Studirende und Aerzte. Von Professor Dr. IMMANUEL MUNK, Abtheilungs-Vorsteher am Physiologischen Institut der Universität in Berlin. Vierte Auflage, mit 120 Holzschnitten. Berlin: Verlag von August Hirschwald. (*Physiology of Man and the Mammalia.* A Text-book for Students and Practitioners. By Professor IMMANUEL MUNK, Director at the Physiological Institute of Berlin University. Fourth edition with 120 Woodcuts. Berlin: August Hirschwald.) 1897. Pp. 633. Price 14*s*.

THE appearance of a fourth edition of Professor Munk's treatise is an indication that it meets the requirements of the German students, and he has done well in correcting and in rendering the teaching of the text-book more precise instead of attempting to make any considerable addition to its size. As the title indicates, the author has introduced many physiological facts that have been drawn from animals, but which illustrate or explain those which are more particularly characteristic of man. Thus, in the account of the blood, the phenomena occurring during the process of coagulation in the blood of the horse are given in some detail, attention being directed to the formation—owing to the slowness with which clotting occurs in this animal, especially if the blood be exposed to cold—of a third layer consisting chiefly of leucocytes intermediate between the plasma above and the mass of red corpuscles below. The rapidity of clotting is given in different animals at four to five minutes for the dog and rabbit, eight minutes in the case of the pig and ox, and fifteen minutes in that of the horse. It is added that, according to Boll, the blood does not coagulate in the chicken before the twelfth or fourteenth day of development. He appears to coincide with the view of Pekelharing and Lilienfeld that the nuclein derived from the leucocytes produces a substance from fibrinogen which does not itself coagulate, but upon the addition of lime salts yields typical fibrin. He gives the proportion of plasma to corpuscles as two-thirds to one-third.

In regard to the restitution of blood after blood-letting he quotes the experiments of Tolmatscheff, who found that in a dog weighing about 24 lb. he was able to take away in seventy-one days, by bleeding the animal about every fortnight, as much as it could be estimated to have possessed at the beginning of the experiment. The body weight of the animal and the quantity of hæmoglobin in the blood rose between the bleedings, whilst the food was kept at the same standard. Hence in seventy-one days it might be accepted that the dog can renew the whole of its blood. A horse can lose upwards of 50 lb. of blood in eight days without harm. On the disputed point of the cause of the first sound of the

Hosted by Google

heart Professor Munk regards it as due essentially to the sudden tension of the auriculo-ventricular valves, but accepts an additional cause in the muscle bruit, whilst he notices the conclusion of Krehl that it is mainly a muscle sound.

The process of gastric digestion is given, not only in man, but in various animals, and especially in the horse, and a curious reason is given to explain why the horse digests meat badly to the effect that it is because the food is retained for so short a time in the stomach, but the author must have forgotten Ellenberger's observations, which show that the remains of the previous meal, and even of the one antecedent to that, may be found in the stomach of that animal. He mentions, however, that in the Steppes the horses are fed on flesh. In the account of the nervous system we observe that Professor Munk does not fully accept the recent views advanced by Cajal, for, although the text speaks of terminal arborescences, the drawing exhibits direct communications between the cells of the anterior and posterior cornua of the cord.

The urine is discussed in the same general manner as the other subjects. A comparison is drawn between the urine of herbivora and carnivora. That of man is then given in full and contrasted with that of the horse. The senses are considered at moderate length, and it is pointed out that th tapetum in the eye is present in carnivora and especially in nocturnal predaceous animals, in the horse and ox, but is absent in man, monkeys, the pig, and generally in omnivora. It occupies an intermediate position between the vascular and the capillary layer of the choroid.

It will be understood from the foregoing comments that Professor Munk's work, whilst it is primarily addressed to the medical student, has also a secondary object which it very well fulfils of being serviceable to veterinary students and to those who are receiving their education at agricultural colleges. To these it will be exceptionally valuable and may be read with advantage in connexion with Meade Smith's and Captain Smith's treatises as giving the most recent results of physiological inquiry.

Analytical Records
FROM
THE LANCET LABORATORY.

(1) DIGESTIVE BISCUITS; (2) NUTRITIVE BEEF BISCUITS.
(G. VAN ABBOTT & SONS, 6, DUKE-STREET MANSIONS, GROSVENOR-SQUARE, W.)

A MICROSCOPICAL examination of the digestive biscuit shows at once its composition and affords some explanation as to why it is called digestive. The biscuits are made entirely from meal and contain the branny particles in a finely divided state, so that while serving as a mild laxative the otherwise irritating property of the bran is reduced to a minimum. The biscuits are desirably crisp and of good flavour and form a very agreeable food when taken with butter. They are useful where a mild laxative is in constant requirement and preferable in many cases to the continuous employment of drugs. The nutritive beef biscuits are said to contain 20 per cent. of Mosquera beef meal, which is a pre-digested meat powder. Our examination fully confirms this statement, since we found the biscuits to possess a high nitrogenous value, while peptones were easily extracted and recognised by simple treatment with cold water. They afford, therefore, a source of reliable and convenient sustenance.

FILMOGEN.
(THOMAS CHRISTY AND CO., 25, LIME-STREET, E.C.)

Filmogen is a clear, mobile, colourless fluid, which has the same boiling point and other characters as acetone. Acetone is, therefore, the probable vehicle for the material, which on evaporation forms a thin, non-sticky, and flexible film, which does not peel off and is not easily removed by simple washing in water or by any chance rubbing. It affords an excellent protective coating for wounds and possesses the advantage that the ordinary antiseptic remedies are generally soluble in the volatile fluid employed. It is useful, therefore, for applying those drugs which are employed as remedies for the skin. A paper on the employment of filmogen was read by Dr. E. Schiff at the recent third International Congress of Dermatology in London.

NORFOLK FOOD OF STRENGTH.
(GOODRICH, HAZEL, AND CO., METHWOLD, NORFOLK.)

This food possesses a pleasant biscuit-like flavour and, consequent upon its method of preparation, contains a very large proportion of soluble carbo-hydrates. It has been carefully cooked, which process improves its flavour besides rendering it more digestible. In addition to wheat flour it contains a definite proportion of oat flour, which, of course, enhances its food value chiefly in regard to nitrogenous and mineral substances. This cereal food enjoys the advantage of being at the same time not only palatable but unquestionably nutritious.

BROMOSAL.
(JOHN RICHARDSON AND CO., LEICESTER, LIMITED.)

This is a brown alcoholic fluid smelling distinctly of tincture of orange and possessing a strong saline taste. As our analysis showed it is a combination of the bromides of lithium, ammonium, and potassium. It is well known that a combination of the alkaline bromides serves more satisfactorily as a nerve sedative or in the treatment of epilepsy than when a single unmixed salt is employed. The above formula, therefore, is one presenting obvious advantages.

FORMOGELATINE.
(KNOWLES AND PHILLIPS, 47, MINORIES, E.)

Formogelatine is a dry, white, crystalline powder, which is, according to our experiments, quite insoluble in water. As its name indicates it is a true compound of formaldehyde with gelatin containing neither an excess of the one nor other ingredient. It is offered as a substitute for iodoform in the dressing of wounds. For this purpose it is well adapted as a drying powder, while doubtless it possesses latent antiseptic properties from the fact of its being a derivative of the powerful antiseptic formaldehyde.

NEAVE'S FOOD.
(J. R. NEAVE AND CO., FORDINGBRIDGE.)

This cereal food is characterised by an excellent rich proportion of nitrogenous food substances and of valuable mineral ingredients, while the carbohydrates are largely soluble and therefore of easy digestibility. It is not deficient in the all-important phosphatic constituents. The flavour of the prepared food is decidedly acceptable and indicates the care and completeness with which the food has been prepared by dry cooking. It presents in acceptable form all the available nourishing constituents of high-grade cereal food.

(1) RESIDUUM RUBRUM TABLOIDS (VENOUS AND ARTERIAL); (2) CASCARA AND BELLADONNA TABLOIDS.
(BURROUGHS, WELLCOME & CO., SNOW HILL BUILDINGS, E.C.)

Blood as a therapeutic agent was reported favourably upon in an original article in THE LANCET of Nov. 28th. In this contribution it was stated that the administration of dry blood residue, in cases of osteo-arthritis was followed by marked improvement. The preparation was given in the form of Residuum Rubrum Tabloids, which consist of the blood residue obtained by evaporating ox blood in vacuo at a temperature not exceeding 100° F. It is suggested that the value of such a preparation must be referred to

Hosted by Google

the secretions of the various ductless glands which blood prepared in this way must of necessity contain intact. We find that the residual blood tabloids behaved chemically exactly as blood dried in the manner indicated. It should be added that tabloids are also made containing the residue of arterial blood, and clinical trial is being made with these and the results should prove of interest. The Cascara Sagrada and Belladonna Tabloids are based upon the following formula: Cascara sagrada extract, 2 gr.; nux vomica extract, ¼ gr.; belladonna, ⅓ gr.; capsicum, ½ gr. Thus the tabloid is designed as a useful intestinal stimulant, while possessing also tonic and laxative properties, which together make the combination well suited in cases of habitual constipation in delicate persons accompanied by feeble digestive functions.

(1) SITOZOEN FLOUR; (2) FARO FLOUR; (3) MALTED INFANTS' FOOD.

(W. HAY, GROSVENOR-STREET, HULL.)

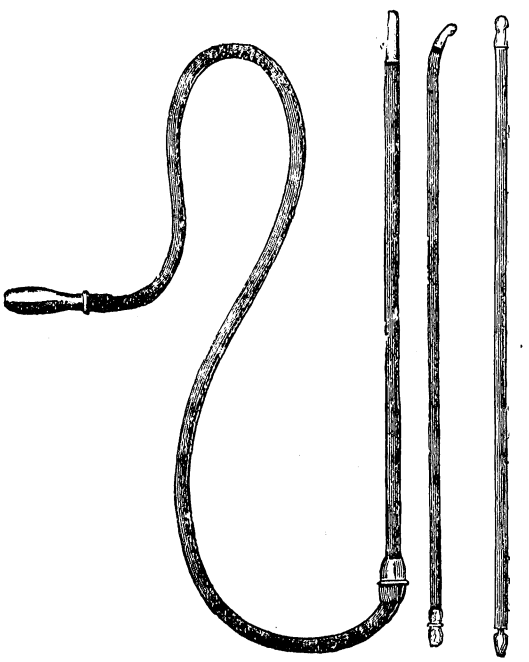
"Sitozoen" flour is nothing lacking in the nourishing food constituents of flour of proper quality. It is enriched by the addition of 20 per cent. of wheat germ, which not only contributes to its nutritious qualities, but makes its flavour more attractive. The preparation, again, is moderately malted, so that there can be no doubt of its high dietetic value. "Faro" flour consists of finely grouud wheat meal and contains, as our microscopical examination showed, the branny particles in a fine state of division. The flour is slightly dark in colour, due to the retention of the germ. It is evidently prepared with care and forms not only a useful food, but one of value also in promoting the normal functions of the intestinal tract. Lastly, the Infants' food is strongly malted, a fact which is evident from the strong and pleasant malty character of the taste. It thus contains a rich proportion of soluble carbohydrates, amongst which may be reckoned malt, sugar, and dextrine.

HANSEN'S DISINFECTANT FLUID AND POWDER.

(HANSEN AND CO., 19, ST. DUNSTAN'S-HILL, S.E.)

There can be little doubt of the disinfectant property of this fluid, since it consists of certain active derivatives of coal-tar dissolved in alkali, and on shaking with water a milky fluid is obtained. A microscopical examination of this fluid shows the active agent to be in a very finely divided state, but not, strictly speaking, soluble. In this condition it is admirably adapted for all disinfectant purposes. A noteworthy feature of the preparation is the freedom from dirty colour of the emulsion produced; it looks, in fact, very like milk. The powder contains a small percentage of the fluid as basis. The absorbent consists chiefly, according to our analysis, of crude sulphate of lime, which to a limited extent is soluble in water. The powder is somewhat fine, so that in distributing it a part floats as dust in the air. This is a probable advantage and due most likely to the dryness of the powder used. The fluid is described as non-poisonous and compared with carbolic acid it is probably considerably less poisonous, but we are not prepared to accept that it is absolutely so.

(1) BEEF AND MALT WINE; AND (2) COCA WINE.



(W. GLENDENNING AND SONS, 9, GRAINGER-STREET, NEWCASTLE-ON-TYNE.)

The results of analysis of the beef and malt wine were as follows: absolute alcohol, by weight 15·83 per cent., by volume 19·49 per cent., equal to proof spirit 34·14 per cent.; extractives, 15·28 per cent.; containing 0·53 per cent. nitrogenous constituents; and ash 0·38 per cent. The ash proved to contain an excellent proportion of phosphates, and the extractive matters on ignition yielded a mixed odour of malt and meat extractives when burning. The presence of a large proportion of phosphates is distinct evidence of the presence of both malt and beef, while the important quantity of nitrogenous extractives affords further confirmation. In the nature of things such a preparation can hardly be expected to contain any important amount of the real nutrient qualities of either beef or malt, but at the same time there can be little doubt but that the wine is of enhanced value from the fact that the extractives of both these foods are present. On this account the wine is distinctly useful as a stimulant and restorative, and it is certain to present an additional dietetic quality over ordinary port wine. Moreover, the wine is said to be made from genuine Alto Douro port. It is evidently prepared with care and with good materials. The analysis of the Coca wine gave the following results: alcohol, by weight 15·08 per cent., by volume 18·58 per cent, equal to proof spirit 32·56 per cent.; extractives, 11·62 per cent.; and mineral matter, 0·33 per cent. We have no doubt that the wine has been made from the leaf of the erythroxylon cocoa and is not merely a cocain preparation. On incineration of the extractive matters a peculiar leafy odour was evolved. On extracting the wine after suitable treatment with ether the alkaloid cocain was obtained. The basis is stated to be real Alto Douro port, as in the former preparation. The wine is therefore prepared from an excellent formula and is well suited where its administration is indicated.

New Inventions.

AN ACOUSTIC BLADDER SOUND.

PROBABLY every surgical instrument maker has been called upon from time to time to make bladder sounds connected with one or two ear-tubes. We have received from Messrs. Krohne and Sesemann a set of three which were made for the late Mr. James Adams, at that time assistant surgeon

at the London Hospital, upwards of thirty years ago. The makers state that they have since frequently made similar sounds to their clients' own designs, varying in form but not in principle.

THE LANCET.

LONDON: SATURDAY, JANUARY 2, 1897.

IT has been our custom in the commencing number of each New Year to devote a few lines to a review of the work that has been done by us in the immediate past as well as to the setting forth of plans for the future, so that the good understanding which we know to exist between our readers and ourselves may be reinforced by comprehension of our motives. Such brief explanation of our editorial proceedings is the more due because of the magnitude of our claims. For we speak as the recognised organ of the medical profession as a whole. No class, no clique, no private interests are subserved by us, but our welfare depends upon a continuance of the support that for over seventy years has been extended to our efforts by the medical practitioners of the United Kingdom. Two things follow directly upon this position. Firstly, we owe to our supporters as well as to ourselves periodical statements of the manner in which we have discharged our great and honourable trust, as well as indications of how we propose to discharge it in the future. Secondly, it is right that we should avail ourselves of any good opportunity that offers itself to invite our readers to tell us of any directions in which they consider our work might be extended with benefit to them.

During the past twelve months the columns of THE LANCET have been replete with the discussion of two sets of grievances far-reaching in their effects, complicated in their causes, and proportionately difficult of remedy. We refer to the troubles that have fallen upon the profession through the abuse of hospitals by the affluent, and through the abuse of medical service by medical aid institutions. Upon a large class of the profession these two sets of abuses have fallen with exceeding heavy hand, and so serious have the effects been in certain districts that we have considered it our duty to make personal enquiry into the matter. The result of our researches into the working of medical aid institutions reached a definite stage on the publication of the book entitled "The Battle of the Clubs," which may be regarded as an *ad interim* report upon the subject and must not be looked upon as our last word. There remains much to be said. We have been able to prove without the shadow of a doubt that certain of these institutions supply bad medical attendance to their clients, appeal for charity on false grounds, provide their rich members with gratuitous treatment to the detriment of their poorer subscribers, and live chiefly upon the talents of their medical officers, whom they sweat and bully. Examples of every one of these disgraceful facts have been forthcoming, and that the administration of certain institutions is free from blame does not affect the important truth that the administration of others is most faulty. We observe that some of our conclusions have been contradicted. We should have paid more attention to our opponents had they elected to contradict the statements upon which the conclusions were founded, and had not officials of the institutions written with unconscious kindness in our columns and proved by their admissions and their language all that we have ever advanced. During the coming year we shall continue to urge on the profession the importance of combining against these institutions. Let thrift among the poor be encouraged. Let the poor man when sick have the same chances as his richer brethren. But let some of the charity come out of the pockets of the various people who masquerade as almoners under quaint titles, but who, so far from giving anything to the institutions, derive from their working the medical attendance for which they can well afford to pay.

The abuse of hospitals by the affluent is the second subject to which we shall specially devote our columns during the coming year, and upon which we shall endeavour to throw light by personal investigations similar to those undertaken in the matter of medical aid institutions. That the out-patient departments of our great hospitals are terribly abused there is no gainsaying, while special hospitals of all sorts, good and bad, necessary and unnecessary, truly eleemosynary or as truly selfish in their foundation, spring up every day and compete under the name of charity with the general practitioner, offering aid to all sick persons not under treatment at the general establishments. Here again we conceive it to be our duty as far as lies in our power to supply facts to the profession. These facts are very difficult to obtain. When we look back on the past prosperity of the medical profession, observe the present, and forecast the impending future, we know that the abuse of hospitals must be rampant. The increase of charitable or semi-charitable hospitals in number, and the increase of the numbers of out-patients at many of them, prove alike the increase in the tendency of the public to desert the family practitioner and to obtain the gratuitous advice which—being more specialised—they consider to be more valuable. There are proofs of the existence of the abuse, but what are wanted are facts to show on whose side the evil lies, so that we may know upon whom to call for the setting in motion of therapeutical action against a deplorably pathological condition. We beg our readers to coöperate with us in an attempt to deal with this difficult subject. To arrest, if only in some degree, the present abuse of hospitals will be to relieve charity from much imposture, to afford the overworked staffs of the honest charities opportunity of doing their appointed work, to divert to the general practitioners the patients whose care should rightly be theirs, and to place the public in a much sounder as well as a much more honourable position for obtaining proper medical relief. If between us we can effect any portion of this great programme we shall deserve what it is our hope that we may all obtain—A Happy New Year.

THE authorities of medical aid associations and of the various commercial companies look on medical work as if it were a purely mechanical routine. Possibly they do not intend to demoralise, degrade, or ruin the relations between a medical man and his patient. But, all the same, such is the tendency of their methods and of the

Hosted by Google

system of medical attendance on the cheap which we have thought it our duty to investigate very specially in the last two years, and on which it is our intention still to throw all the light that patient and continuous inquiry will yield. Medical attendance, to be of real use must be a private and personal matter between the patient and his medical man. All attempts to systematise it in every detail must rob it of half its value. The old club system was liable to this criticism, but not so much as the new attendance on thousands by one man, the servant of a committee of laymen and liable to dismissal on giving any of his many masters offence. On this ground alone we are opposed to medical aid associations and to the exploiting of medical men in such clubs as those worked commercially by laymen in Birmingham and elsewhere and on a huge scale by insurance companies which throw in cheap medical attendance as bait to catch their own sort of business. Instead of huge associations which tend to throw all medical work into the hands of one or two, men and to sweat them out of all health and leisure, everything should be done, in the interest alike of the working classes and of the medical profession, to promote a personal relationship between families and their medical men that will imply some continuity of attendance, some knowledge of the family "constitution," and some human interest such as does not attach to crowds.

The present year is likely to be one of great importance in determining the relations of the profession to the working-classes—not that other classes are excluded from the medical benefits of friendly societies, but that we do not care about discussing the relations of the profession with persons mean enough to pose as fit objects for charity to the detriment of the truly poor. The subject is now, for better or for worse, fairly before the public. Some of our leading papers have opened their columns to it, and we cannot doubt that the public discussion of it will show three things. Firstly, that there is no chance of the poorest person not getting consideration from the medical profession, and, if necessary, gratuitous attendance in an emergency; secondly, that the profession, while determined to assert its claims to be paid better by the working-classes, in accordance with the increased wealth of these classes and the increased demands made by them on their medical attendants, is perfectly ready to abate its ordinary charges in accommodation to those who depend on weekly wages of a modest amount; and thirdly, that the just claims of the medical men to be treated as a profession, at once learned and liberal, must be recognised. It will amaze the public to learn—as they will learn from these discussions in the columns of our contemporaries—that friendly societies which count their savings by millions, and which represent classes that organise, and organise effectively, for better pay, have been trying to reduce medical remuneration to a minimum which would degrade a labourer, not to say a mechanic; and that in order to do this they become huge dispensaries for the medical treatment of the public. It will further surprise the public to learn that in order to carry out such a wholesale scheme of medical attendance they employ hundreds, probably thousands, of canvassers, who do not hesitate to invite the patients of other medical men to join a new club to be officered by some young and impecunious medical man. All this will come to light, and we confidently look to our contemporaries to vindicate the claims to fair treatment of a profession so costly to enter and so arduous to pursue, and to which the public looks at all hours by night or day for services on which life or death depends.

We call on medical men in every town and in every country district to be true to their profession. Medical aid associations and all others that depend on canvassing are to be avoided and condemned. No medical man would directly employ a person to canvass for patients. He is not in a better position if he takes the patients of other medical men procured by the canvassing agent of an association. *Qui facit per alium facit per se.* It is a sorry commencement for a young man entering the profession to accept a position which his seniors have declined in self-respect and in vindication of their rights. He may by so doing get an immediate advantage at the cost of his profession. But he will never look back on such an entrance into practice with satisfaction. What is wanted is a united profession. There are many towns where such union is realised and where this trouble has consequently been avoided. There are others where disunion prevails and the profession is being degraded. No action of the medical authorities will avail if medical men do not stand together in their respective spheres of influence or if they individually do things and countenance methods which are opposed to the traditions of the profession.

PROFESSOR CROOKSHANK has done so much to call attention to the disease known as actinomycosis that his article which we publish on another page will be read with great interest. It is an admirable review of the subject both from the historical and pathological points of view. There can be little doubt, as Professor CROOKSHANK points out, that many cases of actinomycosis escape recognition and are treated as cases of tuberculosis, sarcoma, or one of the many forms of chronic granulomata. It will probably be within the recollection of many of our readers that when the parasitic nature of the disease was demonstrated by Dr. ACLAND in a case which had occurred in St. Thomas's Hospital there were not wanting those who expressed their belief that the lesion was tuberculous, and who at any rate refused to acknowledge its parasitic origin. That cases have occurred in this and in other countries which have been observed and recorded, but of which the true nature has not been recognised, is evident from the fact that LANGENBECK in 1845, LEBERT in 1848, and Mr. T. SMITH in 1855 made drawings of radiating bodies found in pus or granulation tissue which were without doubt actinomycetes. It is only one more instance of the comparative frequency of rare diseases—"rarity" in many cases, at any rate, depending more on the non-recognition than on the non-existence of a malady. The study of actinomycosis from the point of view of comparative pathology is full of interest, since not only is the disease common to man and cattle, but it is probable that it affects horses, dogs, pigs, and elephants. Sufficient evidence has not yet been collected to enable us to state with anything like precision whether the organism found in

Hosted by Google

these different species of animals is identically the same, and whether the small variations in structure are only due to the fact that the conditions of growth are not in all cases identical; but it would seem to be certain that a considerable number of granulation tumours which are found widely distributed in the animal kingdom are due to specific organisms which, if not identical, are at any rate closely allied. The relation of actinomycosis to "Madura foot" has occupied the attention of many writers, and though it is probable that the two diseases are closely related, it is, as far as present knowledge goes, improbable that they are caused by the same organism, and this supposition receives confirmation from the experiments quoted by Professor CROOKSHANK, which lead him to the conclusion that the streptothrix Maduræ has not been proved to be transmissible to the lower animals.

Professor CROOKSHANK speaks as a pathologist rather than as a physician, and he does not therefore go into the question of treatment. It is important that as soon as the diagnosis of actinomycosis is established the part should if possible be removed, and this for two reasons: firstly because the disease is, by removal, capable of cure, and secondly because its method of spread is but little limited by anatomical boundaries. The organism infiltrates and penetrates all tissues with which it comes into contact, affecting indiscriminately bones, soft parts, and viscera, so that if left to itself its spread is little likely to be checked, and the foci of disease may be rapidly and widely disseminated by metastasis through the vascular system. If the parts affected are inaccessible to operative measures iodide of potassium should be administered in increasing doses up to the limit of tolerance, for the organism appears to be of low vitality, and there are grounds for believing that its spread may be checked, and possibly entirely prevented, by the use of this drug, especially if associated with the free use of antiseptics, such as iodoform or perchloride of mercury, applied locally to the diseased structures.

THE biography of THOMAS WAKLEY[1] completed in our last number is far from completing the record of one of the most remarkable personalities in the medical history of this century. Endowed with brilliant talents as an orator, indomitable courage, and original enterprise, he started an era of reform in the constitution of our medical schools, hospitals, and colleges of which the last chapter can never be written. The man who, by devotion to science and by assiduous clinical study, adds a new discovery in fact or law to medicine assuredly confers a benefit on mankind; and if a scientific discovery be prolific, as every truth is, so it may justly be said that the man who clears away the obstacles which harass or block the path of medical instruction also does work prolific of good. No man has surpassed WAKLEY in this work. He undoubtedly deserves the credit of being the greatest of all medical reformers. Every medical practitioner of the present generation owes more than can be well expressed to his clear, intuitive genius, to his bold, vigorous, and successful struggle against the abuses which marked the administration of our hospitals and other medical institutions when he began his career. The road to distinction and emolument lay at this time through nepotism, sycophancy, and jobbery of the most ignoble kind. Such a road was naturally repulsive to men of sterling merit and independent spirit. And one direct consequence was that medical instruction, hampered from the very beginning, necessarily imperfect, often simply dogmatic, made a bad foundation for the growth of science. It is certainly true that in spite of all the difficulties interposed by the narrow, irrational policy so rampant in WAKLEY'S time, many gifted men, breaking through the trammels of that policy, distinguished themselves and made important contributions to science. But it is not less certainly true that the diffusion of sound, practical clinical knowledge and skill through the body of the profession, whose immediate duty it was to apply the resources of science to the relief of suffering man, was most seriously obstructed. Thus the growth of science was terribly nipped at the very source. The number of those who might aspire to scientific achievements was unduly limited, and the mental equipment and physical training for the task was thwarted by imperfect, often bigoted, teaching.

The man who led the way and took a resolute part in removing the obstacles to sound and free education is therefore justly entitled to an honourable place amongst those who have earned the gratitude of mankind by diffusing and enlarging the blessings of science. WAKLEY opened the road to many which before was only trodden by a few. A glance back at the early chapters of the biography will reveal the abuses which he so successfully assailed. Some of these abuses still exist in diminished force and still invite steady and persistent attack; and this movement we are happy to see has been taken up by the Associations of Fellows and Members of the Royal College of Surgeons of England, for medical reform is a prime condition of scientific progress. It was through THE LANCET that WAKLEY'S most effective blows were struck. It was a weapon always to the front, giving no rest to the enemy. His next step towards the emancipation of the profession from the tyranny of the corporations and the hospital incumbents was his contention for the special fitness of medical men to be coroners. And he proved his contention by his personal example. He turned his experience as coroner to good account in asserting and advancing the just claims of his medical brethren to reasonable fees for attendance as witnesses and for performing necropsies. Before his time a coroner's inquest was often a sorry farce. The cause of death—the first object of inquiry—was often assumed, declared, or evaded on the most flimsy and arbitrary grounds. The appeal to science was not only a means of safety to the public, but, as he always said it would be, an opportunity of advancing science. He not only opened up a new field of learning, usefulness, and dignity to the profession, but extended the sources of knowledge, for it is before the coroner's court that the science and art of forensic medicine find the most frequent and often the most useful application. A third great event in his career was his election to Parliament. If this event gratified personal ambition it also gave him further power in proving that the interests of the public were closely linked with those of the medical profession. In the House of Commons he was conspicuous as

[1] See also page 55.

Hosted by Google

an earnest reformer, not alone in medical affairs, but in general politics. He attracted the attention of the House by his zeal, his ability as a politician, and by the force and charm of his eloquence. In doing this he again advanced the claims of his professional brethren to public esteem and fuller representation.

Flagrant wrong is not to be righted by silken, smooth-tongued appeals to the wrong-doer, but by fearless denunciation and strong persistent action. No man more thoroughly believed in this axiom than THOMAS WAKLEY and no man ever gave it more resolute action. No wonder, then, that an opponent so outspoken, so uncompromising, did not fail to arouse envy venting itself in rancorous slander. But any man might well be proud of the generous and noble testimony to his work publicly given by a political opponent, the Leader of the House, the great statesman, Sir ROBERT PEEL. It may be said that in founding THE LANCET, in getting made coroner, and gaining a seat in Parliament he sought and satisfied personal interests and ambition. But to rest here is to take a narrow view of the career of a man fired with the enthusiasm of genius, labouring to uproot evil and to establish truth. Every successful combatant in civil, military, political, and scientific warfare in a great measure selects his own battle-fields and fashions or makes his own weapons. These weapons are an integral part of his being. Rightly viewed, then, THE LANCET, the coronership, and the seat in Parliament were essential weapons for accomplishing the work upon which he had set his soul. And all these weapons are still at work by inheritance, by example, and by trust. We may well say, "He lives in fame, though not in life."

Annotations.

"Ne quid nimis."

SEASONABLE CLEMENCY.

COLONEL WHITE and Colonel Grey were released from Holloway Prison on Saturday morning last, their sentences having legally expired. No excessive soft-heartedness, no political bias of one sort or another, and no particular disposition of investments will be required to make general the feeling of pleasure that two more of the Transvaal offenders are free; for whatever the individual complicity of Dr. Jameson's officers in plots, whose existence has yet to be proved before a Select Committee, we cannot escape from the feeling that all but one of the raiders acted under orders. They were seconded from the army to obey those orders, and if they had not done the thing for which they have been punished they would have been disobedient servants. They were caught in a logical dilemma, where the alternatives presented were equally conclusive against them, and without discussion of what punishment, if any, they deserved, we can all rejoice as each one goes through the ordeal and emerges safely. But there is a reason which will particularly appeal to readers of THE LANCET for being glad to learn of the freedom of one of these officers. Confinement had told terribly upon Colonel Grey. He went into Holloway last July weighing fourteen stones; he has left Holloway weighing eleven. What this loss of weight indicates where the loser is not a gross man, but, on the contrary, in hard fighting trim, can be told in a few words. It indicates that confinement has dealt too severely with Colonel Grey, and that what was designed to be salutary chastisement has proved to be torture. It indicates more certainly than streams of supplication from a prisoner's lips a sickness of heart as well as a sickness of body. It indicates that if Colonel Grey's sentence had not fortunately expired Government would have been compelled to relent towards him. With diffidence, but with certainty that we are speaking from sound medical judgment, we would put forward in behalf of the two remaining prisoners a plea for clemency which we know that they will never bring themselves to utter. It would be a terrible thing if the punishment of these unfortunate officers should result in a permanent injury to their physique, yet this may result despite the assiduous and undoubted skill of the medical officer of Holloway Prison. Justice must be done, and the law for the rich must be the law for the poor. This is the wisdom of every sound social scheme, to which no one should lightly ask a Government to run counter. But having regard to the sufferings that Colonel Grey must have endured, we wish to know whether it would not be possible to anticipate the occurrence of such mischief in the cases of the remaining two prisoners. Sir John Willoughby is understood to be a tougher subject than Major White and to be more able to bear his punishment phlegmatically. We are in a position to state that Major White's condition gives grave cause for anxiety. He is weak, nervous, and sleepless, and the ordeal of imprisonment has proved too much for him. Has not the cause of justice been vindicated sufficiently? If so, we would earnestly beg the Government to let these two remaining victims of their obedience go free. It was not intended to punish them in such a way that even the remotest chance of a permanent break-down of health should occur. Justice has been done: let clemency begin with the New Year.

THE QUEEN'S COMMEMORATION FUND.

THE unparalleled length and glory of Her Majesty's reign is a matter for commemoration in the most impressive manner. Money should be forthcoming in any needed quantities, but it is very desirable that it should not be given hastily. There is a tendency to "rush" in this matter. To be first in the field is an obvious advantage, and those with pet schemes are already acting on this principle. Still, those who have the means and the disposition to contribute to some object that will worthily signalise an unprecedented event in English history will take time to think. The object should be one which expresses the progress and the humanity which have been the notes of Her Majesty's reign and to which she and her family have made the most helpful and sympathetic contributions. It may well be that more than one great object will be proposed. But it is sincerely to be wished that some central body of wise and influential persons in whom the public have confidence may be chosen to invite contributions to a central fund to be devoted to certain objects. The use of such a central body would be to define these objects and to try to define the proportional importance of them. All, of course, would have to be done with the approval of Her Majesty, but doubtless that would be forthcoming for any purpose which seemed to commend itself to the public mind. There is one purpose pre-eminently calculated to excite public interest, the achievement of which would shed a lustre on the Queen's reign and the century which is nearing its end. We mean the removal of the debt on our public voluntary hospitals. If any institutions represent the progress and the humanity which have marked the Victorian era they are our hospitals, where the pain of operations has been annihilated and the success of measures for the saving of life has been developed to a degree

Hosted by Google

scarcely equalled in all the previous centuries. The debt on these hospitals is having a discouraging and in some cases a demoralising effect on them. They are ceasing to be institutions only for the poor, but are catering for those who are not poor, and are even trying to make a little money out of such catering to maintain what remains ostensibly for the use of the poor. Half a million of money would go far to free these institutions from debt and give them a new start for a new century. We urge this great claim on the people of England and especially of the metropolis. We do not wish to be drawn into any disparagement of nursing institutions, which have been somewhat prematurely put forward as a primary object for the loyal enthusiam of the subjects of Her Majesty in this memorable year. We cannot admit that they have any such claim as hospitals have. They spring out of hospitals and find in hospitals the training which makes them useful. Every district with a little self-sacrifice and without any heavy responsibility can secure and can pay for its own trained nurse for the poor. To put nursing institutions before hospitals at a supreme moment like this will be robbing Peter to pay Paul. Besides they have had their turn. At the Queen's Jubilee Her Majesty most graciously gave £70,000 to found the Institute for Nurses for the Poor, and a great impetus to the supply of this want has been given by her generosity. About 600 nurses have been so supplied to places all over the country. It is now the turn of hospitals and their claims are overpowering and unanswerable.

OYSTERS AND DISEASE.

MR. WYNTER BLYTH, medical officer of health of Marylebone, refers in his monthly report for November to a series of six cases of gastro-enteritis, one of which subsequently developed enteric fever, in which the evidence pointed strongly to the consumption of oysters as the cause of the mischief. The six persons in question dined at a well-known London restaurant and the only articles of diet which they consumed in common were beef and oysters. The oysters are stated to have come from Colchester, and Mr. Blyth refers to Dr. Bulstrode's detailed report on that locality to show that thereabouts there are "layings" liable to sewage pollution. It is, however, necessary to differentiate in the matter of layings in the vicinity of Colchester, since the fattening beds of the Colchester Oyster Company, as well as their storage pits, appear from the Local Government Board report to be practically free from pollution. Unfortunately, however, in that part of Essex there are certain pits and layings which do not belong to the Colchester Oyster Company, which were at the time the report was written liable to contamination in a high degree, and it is, too, further pointed out in the report that no oysters should be despatched direct to market from the bed of the river Colne itself. We would especially insist upon the importance in all cases such as those referred to by Mr. Blyth of ascertaining, if such be possible, the exact whereabouts of the pits or layings from which the suspected oysters were obtained. Unless this step be taken injustice may be done to oyster merchants and others whose beds, &c., are free from pollution. Mr. Blyth also states that in some other cases of enteric fever notified in November the sufferers were in the habit of consuming considerable quantities of oysters. In connexion with the general question of oysters and disease, Mr. Blyth points out that accidents such as those to which he has referred may be obviated by a proper supervision of the oyster industry. This subject we recently dwelt on in a leading article in our columns,[1] and we can only reiterate that fresh measures of control must follow upon the Local Government Board report. We notice that in some quarters the oyster merchants even go so far as to deny the existence of layings and pits liable to pollution. Those who do thus are simply aiding and abetting the destruction of an important national industry; but, on the other hand, those—and they consist of the more intelligent men in the trade—who are anxious to bring about the closure of the polluted layings and pits are taking the proper steps to re-instate the industry in the confidence of the public.

[1] THE LANCET, Dec. 12th, 1896, p. 1695.

PRIVATE HOSPITALS *v.* MEDICAL PRACTICE.

IT would appear from some of the methods employed in the name of medical practice that one of the least essential aids in this department of work is the practitioner himself. Mutual interests depending on long acquaintance and intimate technical knowledge are no longer needful, it would seem, to bind together his patients and himself, nor indeed for that is any personal bond of value. Such, at least, is the impression conveyed to a casual reader by such circular addresses as that lately issued by "The London Galvanic and Massage Hospital." This institution, which is, of course, self-supporting, represents the newest departure in medical touting. It is virtually a pay-hospital, of the kind which its title suggests, in which the fee is regulated by the pocket of the patient. The hospital, according to its published prospectus, is under the control and supervision of a solitary director, who is responsible to no authority but his own. The nurses employed are, moreover, as regards their training, native to the establishment. As a bid for the patronage of credulous persons this venture may have some success. The attempt, however, is at least a bold one in times when our national intelligence is supposed to be increasing, when the competence of medical practitioners is as general as it is admittedly high, and when massage and electricity form part of the well-worn armament of medical skill. There can be no doubt, therefore, that touting such as appears in every line of the comment before us, when viewed in connexion with such considerations as these, ought to be utterly discredited by rational people.

TRAUMATIC CANCER.

MANY parts of the East of London are infested by gangs of roughs, who attack wayfarers, maltreat and rob them, and yet, so far as police-court cases show, it is only occasionally that any punishment follows these deeds of violence. It is easy to understand that the police find great difficulty in apprehending any of these men, for they disperse rapidly in the dimly-lighted streets and as readily reassemble. Numbering often more than a dozen, they can without any anxiety as to the result set upon anyone they may meet, and unless he submits quietly to be robbed they quickly render him insensible by blows and despoil him of his money and valuables. The danger is a growing one, and in our opinion needs exceptional measures for its repression. Some of the accounts read more as if they had occurred at the commencement than at the close of the nineteenth century. These remarks are called forth by the report of a recent inquest, at which it was stated that the woman on whose body the inquiry was held had been severely kicked by a gang of men about four months before death. A fortnight after receiving the injury a cancer appeared in the right breast, and from this she died. The question whether mechanical injury can cause malignant disease is a very interesting one, but in this case it may be definitely decided that the injury had nothing whatever to do with the appearance of the cancer. The short interval—two weeks—between the blows and a noticeable growth is far too short, and, moreover,

Hosted by Google

at the necropsy it was found that secondary deposits had appeared "all over the body," but "especially in the lungs"; such widespread extension of malignant disease must certainly have taken more than four months. But apart from this case there exists a very general opinion both among the public and in the profession that a local injury, such as a blow, is a very common starting point of a malignant growth. That mechanical injury, such as the rubbing of a rough tooth, may lead to the appearance of epithelioma of the tongue is, of course, certain; but the proof that a blow on the breast without any skin lesion can give rise to cancer is not satisfactory. If such an injury has any influence in predisposing to the appearance of malignant disease it is probably due to the production of a *pars minoris resistentiæ* which is favourable to the development of a new growth. The frequency with which a blow is put forward as the cause of a cancer of the breast is probably to be attributed partly to the popular belief in its efficacy and partly to the satisfaction which most people feel in accounting for any disease from which they may suffer. Blows on the breast are far from rare, and the probability of a blow having preceded the development of a new growth is very great.

SYSTEMATIC POISONING.

WE read from time to time of systematic traders in murder and robbery and professional poisoners, but we question whether it would be easy to beat the history of crime in this direction recently brought to light in the trial of a native prisoner at a court in Cawnpore. The criminal in this instance is a native of India, one Bhadaiyan Kori, who systematically carried on his trade as a professional poisoner for a considerable time for the purposes of plundering his victims. He employed the agents usually adopted in India for the purpose—viz., dhatura and probably arsenic also. His method was to join travelling natives and to mix his drugs with their food in order to rob them of their clothing and effects. The evidence against him was of a conclusive kind, and as he made a complete confession of his crimes there is no room for doubt about the matter. It is, we believe, a curious fact that in cases of poisoning by dhatura in India a difficulty sometimes arises from the poisoner cunningly simulating illness and imitating the symptoms of the poisoned so that a medical man is likely to be deceived and to apply the same remedies to all alike—to the criminal poisoner and his victims. But there was nothing of this sort in the present case.

VACCINE VIRUS IN LIQUID FORM.

OUR New York correspondent writes:—"The Health epartment of New York has determined the most valuable part of a vaccine vesicle by the following experiment. A typical vesicle was chosen, and the crust, the underlying pulp and base and the serum exuding after the former were removed were collected separately. Each was mixed with glycerine in the proportion of 60 per cent. vaccine matter and 40 per cent. glycerine, then thoroughly comminuted in a mortar, and the products were used in the multiple vaccination of children. The pulp showed by far the best, the crust the next, and the serum the poorest results as determined by the percentage of successful vaccinations. It was concluded that the largest proportion of the active virus is contained in the pulp. Therefore the virus now used is in the form of a glycerinated vaccine pulp. Before using the virus derived from an animal, first, the animal from which it was obtained is sent to necropsy and the organs are examined for any evidences of disease; and, secondly, two samples are given, one to the bacteriologist and the other to the medical tester of virus, and no virus is issued unless the reports of the pathologiist, bacteriologist, and clinical tester are all satisfactory. In all the primary vaccinations made during September and October by the department vaccinators in which the results are known, more than 700 in number, there was not a single failure. The virus is a syrupy, opaque, brown emulsion of uniform consistency. It is put up in capillary tubes containing each enough for a single vaccination and in phials of two sizes, one containing one-fifth of a cubic centimetre for ten vaccinations, and the other containing one cubic centimetre for fifty vaccinations. In using the new virus the skin is scarified in the usual way and a drop of the liquid virus (discharged from a capillary tube by blowing out the contents with a rubber tube furnished for the purpose) is then thoroughly rubbed into the scarified area with a slip of wood, which accompanies each tube."

PUERPERAL MORTALITY.

WE have received a little pamphlet by Dr. W. Williams, D.P.H., on Puerperal Mortality, reprinted from the Transactions of the Epidemiological Society of London, and although, as he tells us, he has nothing exactly fresh to communicate, nevertheless, the fact that 4000 mothers in England and Wales still die in childbed every year is one that more than justifies renewed efforts to elucidate the causation of such a lamentable mortality with a view to its prevention. Puerperal mortality may be divided into two classes—the mortality due to puerperal fever, and that due to what is called "the accidents" of childbed, such as placenta prævia and eclampsia. During a period of forty-eight years—from 1847 to 1894—the mean annual mortality rate for puerperal fever has been 2 per 1000 registered births, and that for the "accidents" of childbed has been 2·9. If the period of forty-eight years in question be divided into four periods of ten years each and one period of eight years, and the mortality during each such period for puerperal fever and for the accidents of childbed be tabulated, it will be seen that while during the period 1847–1854 the puerperal mortality from "accidents" of childbed was 3·01 per 1000, it subsequently declined till during the period 1885–1894 it stood at 2·41. On the other hand, as regards the mortality from puerperal fever, the rate which during the period 1847–1854 was 1·72 had increased till during the period 1885–1894 it had reached 2·53. There is no doubt that to some extent this apparent increase may be accounted for by the fact that since 1881 the Registrar-General caused letters of inquiry to be sent in cases where women of child-bearing age were certified as dying from peritonitis, pyæmia, &c. Still, as Dr. Williams says, this improved certification has now been many years in operation, and we might have expected to see some decline in the rate; but, on the contrary, the fact is that from 1881 to 1894 "there has been a higher sustained mortality (from puerperal fever) than in any other previous or corresponding period." That puerperal fever is both more liable to attack primiparæ, and is also more likely to prove fatal in them than in multiparæ, appears to be certain. No doubt the explanation of this as suggested is the right one—viz., that tears and lacerations are always present to a greater or less extent in primiparæ, while in multiparæ this is not so. Every laceration is a possible source of danger, since it may allow of the entrance of septic matter. As regards the greater mortality of puerperal fever in primiparæ, Dr. Williams is able to speak of an epidemic that came under his personal investigation. In twelve cases in which primiparæ were affected eight (or 67 per cent.) died, while in fourteen cases where multiparæ were affected four (or 28·6 per cent.) died. Full particulars of this epidemic are given and are well worth attention, though the main points are sufficiently familiar.

Hosted by Google

Thus, for instance, nearly all the fatal cases in each locality were attended by the same midwife. An interesting point is that a number of cases attended by the infected midwives escaped; but this may be easily accounted for by supposing that in such cases there were no lacerations suitable for the entrance of septic poison, or that, owing to the midwives' hands being accidentally cleaner than usual, the supply of septic matter was temporarily deficient. Dr. Williams in investigating this epidemic interviewed some of the midwives concerned, who were so ignorant that they admitted that they did not even know that they might have been the means of spreading the disease, and of course they knew nothing of the means of disinfecting themselves. Yet puerperal fever has been clearly shown to be a preventable disease. It has been practically banished from the best managed lying-in hospitals, where, apart from the antiseptic system, the conditions are necessarily extremely favourable for its prevalence. The sustained mortality due to the prevalence of puerperal fever *outside* lying-in hospitals shows that the conditions under which women are confined outside these hospitals have not shared to the same extent in the improvements effected inside them. The great point to be insisted on is that in all cases personal responsibility should be felt as regards puerperal fever. If adequate antiseptic precautions are adopted by the person attending a midwifery case, in the way especially of thoroughly scrubbing the hands and nails with soap and hot water, and subsequently, after rinsing off the soap, scrubbing them in a solution of corrosive sublimate 1 in 1000 *before* making any examination, then the mortality from puerperal fever will steadily decline outside lying-in hospitals as it has done inside them—and not till then.

"CHEAP CONSULTANTS."

AN edifying correspondence has recently (Dec. 24th, 26th, and 28th) appeared in the *Times*, following a leading article in that journal in which the writer deplored the frequency of errors of diagnosis in medical practice. Dr. Balmanno Squire, with an enthusiasm which reminds one of "nothing like leather," recommends as a remedy the calling in of a consultant as a routine practice to settle the diagnosis, considering that "practitioners of even less than the average attainment are competent when once the question of diagnosis has been accurately solved to conduct the treatment of the case on, at the least, fairly sound lines." Without stopping to discuss whether treatment of a recognised disease is even comparatively such a simple matter, we may examine the way in which Dr. Balmanno Squire proposes to put his remedy in the way of everyone. The well-to-do are still to go to the senior consultant with fees as at present, while for others an intermediate class of "cheap consultants" should be formed composed of younger men who have "taken up some speciality and would see patients at a half or a quarter of the fee charged by the present consultant." He thinks that "the practitioner need not fear that he will lose his patients to the cheap consultants." But there seems even now to be a widespread conviction among practitioners that they do lose many of their patients to high-priced consultants. We regard the suggestion as an undesirable and impracticable one, which would intensify the jealousy which from time to time shows itself, and the development of specialisation which is implied has probably more drawbacks than advantages. The ranks of consultants are now filled by those who have achieved success and those who, hoping ultimately to do so and having facilities for clinical study, are endeavouring to create a reputation. The lowering of fees for these junior men might give them less leisure for the investigation and study which render their opinion valued later; it would certainly lower their own status and would lead to incessant friction between all classes of the profession. But it seems to us that Dr. Balmanno Squire, and perhaps the general public, unduly belittle the general practitioner. The mistakes in diagnosis do not always lie at his door, and many of the alleged cases of wrong diagnosis are due to misunderstanding, the consultant speaking of "displacement of bone" where the practitioner had spoken of "dislocation," or of "facial paralysis" when the local medical man had diagnosed "Bell's palsy." The reprehensible practice of patients going on the sly to obtain a consultant's opinion, without letting him have the advantage of even a written statement of the previous history, is responsible for many of these misunderstandings and supposed "mismanaged cases." The value of a second opinion is often extreme, but its full value can only be obtained by a consultation in the full sense of the term. The frequency of these "mismanaged" cases seems to be much exaggerated and to be daily diminishing as the education of each practitioner is now so wide and complete, and we believe that the way to remove the reproach is to improve the practical teaching of the student and not to adopt some revolutionary measure, such as the creation of a large class of "cheap consultants," with a boundary line between them and general practitioners even less definite than that which now separates the two classes.

SYRINGOMYELIA WITH ARTHROPATHY.

IN the December number of the *American Journal of the Medical Soiences* Dr. Dercum and Dr. Spiller record a very important case of this rare and interesting disorder. The patient was a man aged forty-five years, a native of Sweden, unmarried, and a labourer by occupation. There was nothing significant in his family or personal history until about three years before his admission to hospital, when he strained his back with some heavy lifting. He was in bed for a day, but experienced no subsequent ill effects until about the time he was admitted in 1883, when he began to have pains in his legs, a tight feeling round his waist, and weakness in his lower extremities. He gradually after this developed the usual signs and symptoms of spastic paraplegia, rigidity and powerlessness of the legs, loss of control over the sphincters, exaggeration, followed by disappearance on account of excessive rigidity, of the deep reflexes, and marked impairment of sensibility on the legs. It was also found that the sense of temperature was entirely lost in the right arm and the right side of the neck, and there was some analgesia over this limb. In 1888 it was observed that his right shoulder had become swollen, the joint surfaces grated, and there was some effusion into the joint. There was no pain associated with the changes and the effusion went on increasing, and finally there was rupture of the capsule and infiltration of the subcutaneous and muscular tissue. There were no other peculiar clinical features in the case except the occasional development of small abscesses and of bed-sores. The psychical condition was one of considerable irritability. He finally died from exhaustion in 1895, nearly thirteen years after his admission. On examination of the spinal cord after death there was found to be in the terminal part a considerable area of gliosis around a small central cavity. In the sacral cord the cavity was larger, but this was not an extension of the central canal, which was occupied by a mass of proliferated cells. In the lumbar region the cavity was larger and there was degeneration in the crossed pyramidal tracts. There was now considerable thickening of membranes extending as high as the upper dorsal region. Throughout the thoracic region the cavity extended through the posterior horns to the pia mater, and above the first thoracic segment the cavity became limited to the right posterior horn; the

Hosted by Google

degeneration in the lateral columns was still present, but much more extensive on the right side than on the left. The right anterior column was also degenerated and so were the columns of Goll. The details of the description are very interesting and so is the interpretation of them which the writers offer; and not the least important part of the paper is the description of the condition which was found in the affected shoulder-joint. There was complete disappearance of the head and surgical neck of the humerus and minor alterations in the other bones. Such a case as this carefully observed clinically during a prolonged period and systematically examined after death is extremely valuable, and we congratulate the writers on the important results which they have achieved by the care and accuracy with which they have made and recorded their observations.

ARSENICAL SOAP.

WE are glad to see that the manufacturers have been touched by the recent prosecutions in regard to Arsenical Soap. In the *British and Colonial Druggist* of Dec. 25th are two advertisements which show very well the harm which such contradictory decisions as were given upon Dec. 6th and Dec. 12th bring about. Advertisement No. 1 says:—

ARSENICAL SOAP.
DR. MACKENZIE'S.

DEAR SIR,—With a view of preventing any possible further prosecutions under the Food and Drugs Act, Wholesale and Retail Houses are requested to immediately exchange all Dr. Mackenzie's Arsenical Soap which they have in stock for that which we are now manufacturing under a new formula, and which is guaranteed, amongst other ingredients, to contain a uniform though small quantity of Arsenic easily found by Analysis. ..... I am of opinion that it is better to immediately exchange all present stock for that which we are now manufacturing with, amongst other ingredients, an increased amount of arsenic, and which will fully comply with the Food and Drugs Act. Chemists can send what they have in stock direct to me, and also advise by post the quantity returned, and I will, of course, pay carriage, and exchange it. The new soap will in future have printed on the labels "New Formula," so that there shall be no chance of retailers selling by mistake any more of the old stock. I will indemnify all chemists and druggists against prosecution, provided that they will exchange their present stock immediately, and sell only that which bears the imprint on the outside of label "New Formula," and where required will give a warranty that Dr. Mackenzie's is a genuine arsenical toilet soap.

S. HARVEY.

Possibly now if this soap is used indiscriminately by the public there will be some cases of arsenical poisoning. That, however, is for the public to guard against. Advertisement No. 2 says:—

ARSENICAL SOAP.
JAMESON'S.

The Proprietor of the above preparation calls the attention of the Chemists of the United Kingdom to the decision given at Brentford on Saturday, 12th December, 1896, in which it was held that the presence of Arsenic, even the minutest quantity, was sufficient to exempt dealers from prosecution under the Food and Drugs Act. In the manufacture of Jameson's Arsenical Complexion Soap the machinery is so perfect that not only is Arsenic to be found in each tablet, but severe testing has shown that the percentage is also uniform, and consequently each and every tablet may be sold with the utmost assurance; and in order to make the trade feel as confident as does the Proprietor, he takes this opportunity of informing them that he will in every instance defend them and indemnify them should action (which after the judgement quoted is not very likely) be taken against them, and, further, he is prepared to give them a warranty with each delivery of the Soap, which the trade has only to show to the authorities to immediately quash the indictment. It is not for the Proprietor of Jameson's Arsenical Complexion Soap to instruct the trade as to the manner in which it shall conduct its business, but he takes this opportunity of declaring that he will, after this notice, defend any Chemist against prosecution under the Pharmacy Act, provided he has himself fulfilled the statutory obligations.

Please note that the holders of Jameson's Arsenical Complexion Soap are requested to send a post-card notifying the same, and a warranty, which, as before stated, is a certain protection against prosecution, will, with a supply of labels for complying with the Pharmacy Act, be forwarded per return.

W. JAMESON, * * * * * *

We cannot see why sellers of mixtures should not be compelled to label their preparations—e.g., "Arsenical soap. This soap contains $\frac{1}{10'000}$th (or whatever may be the proportion) of a grain of arsenious acid to the pound." "Finest East India coffee. This coffee is a mixture of three parts of chicory to one of coffee. It draws a fine, rich, syrupy liquor, &c., &c. It goes much further than Mocha." If this were made the law purchasers would at least know what they were buying.

THE ROYAL INSTITUTION OF GREAT BRITAIN.

THE programme of lecture arrangements before Easter has just been issued. The Christmas lectures by Professor Silvanus P. Thompson commenced on Dec. 29th The subject is Light, Visible and Invisible. The lectures will be continued on Jan. 2nd, 5th, 7th, and 9th, 1897. Professor Augustus D. Waller will commence a series of twelve lectures on Animal Electricity on Jan. 19th and Lord Rayleigh will discourse on Electricity and Electrical Vibrations in a series of six lectures commencing on March 6th. The Friday evening lecturers embrace the names of Professor Dewar, Professor John Milne, Mr. Shelford Bidwell, Sir Wm. Turner, and others. Among the subjects to be dealt with are The Properties of Liquid Oxygen on Jan. 22nd, Recent Advances in Seismology on Feb. 12th, and Curiosities of Vision on March 5th.

THE LANCET RELIEF FUND.

THE report of the almoners of THE LANCET Relief Fund appears to-day in another column and shows that the modest but, as we trust, serviceable charity which they dispense is still drawn upon to the full extent of the resources placed at their disposal. A comparison of the present report with those of previous years shows that of the two classes of benefits provided gifts tend to prove more serviceable than loans. The loans, though less numerous than the gifts, are on an average larger in amount, and at the end of their first year of administration the almoners reported that they had actually exceeded the gifts—by a few shillings—in their aggregate sum. That, however, has not happened in any subsequent year, and taking all the eight years together we observe that out of a total disbursement of £2531 there has been given £1488 10*s*., lent £1042 10*s*. Repayments on account of these loans have now come to be a source of income to the fund, which was in this way augmented during the past year by £25 10*s*. As the loans are made free of interest these repayments represent only the return of capital, and do not form a source of income in the ordinary sense of that word. A very satisfactory feature of the present report is, that although the number and amount of the benefactions have been as great as ever, the number of applicants has been smaller than on some previous occasions, and notably than in 1895. This has a double significance. In the first place it follows from this that the number of cases in which it has been necessary to turn an applicant away unrelieved has been less. In point of fact, out of thirty-seven applicants twenty-nine, as already mentioned, have been relieved. This is of itself matter for congratulation and it also conveys the suggestion that the scope and purpose of the Fund are coming to be better understood than was at first the case. We have had repeatedly to ask our readers to note that only cases of pressing and temporary necessity are eligible and to beg them when asked to recommend an unsuitable case to explain the difficulty at once to the intending applicant and so save further and more serious disappointment. The almoners draw attention to this point again in the present report, and we are glad to draw from their figures the inference that their observations made on previous occasions have produced to some extent at least the desired impression. This work is so intimately associated with THE LANCET that we feel ourselves privileged when noticing it to express our heartfelt thanks to the almoners and auditor who have during the past year officiated in the administration of the fund. Sir John Russell Reynolds has passed beyond the echo of our acknowledgments, but to Dr. Wilks, his

Hosted by Google

successor in the chair of the Royal College of Physicians of London, to Mr. Christopher Heath and Sir William Mac Cormac, who have presided in succession at the Royal College of Surgeons of England during the past year and to Sir Richard Quain, the President of the General Medical Council, who have assisted in the disbursement of the Fund and personally interested themselves in its work of charity, to Sir Henry Pitman, who from the commencement of the Fund has audited the accounts, and to the many brother practitioners throughout the country who have undertaken the duty of investigating on the spot and advising upon the merits of applications we tender our hearty thanks for their valuable and gracious help in the cause of our distressed brethren and their dependents.

THE CHIEF RABBI AND VACCINATION.

THE Chief Rabbi has only done his religion and his co-religionists justice in causing a contradiction to be published to the statement reported to have been made by a Jew that there was a religious objection to vaccination. The Jews are too sensible in their religious views to hold such an opinion. The Chief Rabbi disclaims it altogether through the medium of the *Jewish Chronicle*, and says, with a force that all Christian teachers would do well to imitate: "Since this process [vaccination] has been proved by the most eminent authorities to be a safeguard against small-pox, and inasmuch as an Act of Parliament renders its use obligatory, a Jew who refuses to have his child vaccinated at the proper time is guilty of a grave infraction both of the Divine law and of the law of the land."

J. PICKERING, F.R.G.S., F.S.S., F.S.A., ETC.

THE gentleman possessed of the above array of letters has recently confided in an interviewer at Leicester concerning his treatment of fever. The interview has been published and very interesting reading it is. Mr. Pickering was asked "if he had had opportunities of testing the accuracy of his conclusions ..... and in answer he mentioned a number of cases which may thus be summarised:—

"1. In January, 1895, two cases of chicken-pox were cured in one day by the application of baths.

"2. The same month he was called into the country to see a young woman who had recently nursed a married sister through an attack of scarlet fever. She was sickening for the same disease. Baths were administered at the house of a friend. The first stopped the fever, the patient partook of gruel, a wet compress was applied round the head, and the patient slept quietly. Next morning at 11 she had a second bath, she was down to tea at 5 o'clock, and out the next day.

"3. The next month a maid-servant was seized with fever symptoms. After three baths her health was restored, and during the treatment she attended to her household duties.

"4. In March, 1895, a young girl residing with her parents near Leicester was suffering from all the symptoms of scarlet fever; temperature 102 degrees, bad throat, pains in neck and back, prostrate, sleepless, and depressed. A bath was administered by the mother, which removed the pains, and enabled the girl to swallow better. She had some food and slept; next morning she had a second bath, and in the afternoon a tepid bath. At 4 P.M. she was out with her father for a stroll in the lane."

"Mr. Pickering mentioned other cases of a similar nature, and gave the names and addresses of the persons concerned. Further instances, as stated, have come to our knowledge since from independent sources. In the course of the interview Mr. Pickering spoke of the law of cure. Asked to describe the law, he said:—

"It is the law of elimination, discharging at the skin the special poisons which had gained access to the blood, just as bile is discharged at the liver."

We like the physiology, and we should much like to know whether Cases 2 and 4 had scarlet fever, and if so how many people they infected afterwards. Mr. Pickering is gracious enough to say that it would be better to have a physician at the sanatorium, but he also says "you do not want a medical man to give you a morning bath; the thing is absurd. Then why do you want one to give a bath at any other time?" It would be a pity to spoil this singularly logical argument by any comment. We see by the daily press that the Leicester Corporation Sanitary Committee have decided that "this treatment should, subject to the discretion of the medical officer of health, be fully applied to patients in the hospital." According to Mr. Pickering, "extremes of temperature are destructive of germ or organic life in the blood. Cold water at hot water 36° F., or at 102°, are conditions under which no fever can live." As Mr. Pickering's patient No. 4 had a temperature of 102°, why did he give her a bath? We had thought that 212° or so was the germicidal temperature.

THE PLACE OF CORPORAL PUNISHMENT IN OUR LEGAL CODE.

NOTWITHSTANDING that there still lingers in the minds of some persons an aversion to the use of the lash as a means of punishment, there are not wanting on all hands utterances like the recently expressed opinion of Mr. Justice Day, which advise corporal punishment in certain cases. We admit our sympathy with this latter view on the subject. A sense of degradation is frequently attributed to sufferers from the corporal penalty. But this is in many, probably in most, of the cases in which it has been inflicted an imaginary association. It is hard to understand how so fine a feeling of personal propriety should reside in the violent and criminal assailant of man or woman. The association of such ideas with such practice is itself ludicrous because so forcibly unnatural. Juvenile offenders, on the other hand, must, we should say, be positively benefited by the short and sharp lesson of personal chastisement. They are thus spared that corrupting and enervating contact with prison life which is to their youth like a moral poison. In view, therefore, of the fact that the number of this class of offenders has lately much increased and that by habitual evildoers prison life is even sought for as a species of livelihood we should not be sorry to have an extended trial afforded to the more drastic and more expeditious method of correction. In the case of one cowardly form of crime—garotting—it has already been employed, as our readers are aware, with distinct benefit.

"APHASIA OF THE RIGHT HAND IN A DEAF MUTE."

UNDER this heading Professor J. Grasset of Montpellier publishes[1] a brief but explicit account of a remarkable disability which recently came under his observation. Charcot described agraphia as "aphasia of the hand," says Professor Grasset, but the comparison, though striking and to a certain extent apt, is not absolutely precise. The only true aphasia of the hand is when a deaf mute who has never learned oral speech loses the faculty of conversing manually. Such cases are necessarily extremely rare, and they are likely to become still more so, because intelligent deaf mutes who have not acquired speech are becoming fewer and fewer every day. In order that true aphasia of the hand may be differentiated three factors are necessary. First, an intelligent deaf mute who cannot speak orally; secondly, the incidence of the aphasic condition upon that individual; and thirdly, the non-existence of brachial paralysis sufficient *per se* to account for his inability to converse manually. These three factors are co-existent in the person whose case is given in detail. The patient, aged about fifty years, is a gouty subject and presents all the signs of general arterio-sclerosis. Two years ago the symptoms of progressive cerebral softening set in gradually in consequence of thrombosis of certain arterial branches in the left hemisphere. That there is no sensorial aphasia is evident from the patient's ability to read his newspaper and to understand questions when formulated in the ordinary deaf-and-dumb alphabet. If asked to point out printed words or letters he invariably does so correctly. Formerly he was very active and capable in the conduct of his affairs, and although his memory and

[1] Le Progrès Médical, Oct. 31st, 1896.

Hosted by Google

quickness of comprehension have both failed considerably he still exhibits a fair amount of intelligence. Owing to a combination of circumstances he never acquired oral speech, but it is said that he was able to converse by means of the manual alphabet with exceptional volubility, using his right hand almost exclusively. He could also write very well in the ordinary way, but at present he is incapable of shaping letters with his right hand either symbolically or on paper. When asked to go through the deaf-and-dumb alphabet he can make an A after several attempts, and sometimes a B, but never has any further success; whereas with the left hand he experiences no difficulty whatever. His right forearm is partially paralysed, but far from sufficiently so to account for the agraphia. He uses it when eating and drinking, can grasp an object firmly, raise his hand to the top of his head, &c. The movements of the limb are only partially impeded, whereas the patient's power of expressing himself therewith is totally destroyed. He may consequently be said to furnish an example of true aphasia of the right hand. Professor Grasset finally comes to the conclusion that in a deaf mute a centre becomes developed in the cerebral cortex which presides over manual language, but is distinct from the centre whence the ordinary movements of the upper extremity are controlled. The two centres must be separate from, and independent of, each other, inasmuch as they are susceptible of artificial dissociation through disease. The manual language centre is physiologically allied to that for writing: are they likewise allied anatomically? and ought they to be located in the second frontal convolution rather than in the third? Professor Grasset is of opinion that his case supports these hypotheses, but does not establish them.

MEDICAL PRACTICE IN SOUTH AFRICA.

A CORRESPONDENT writes to us:—"The following facts may prove useful to those who look on South Africa as a good field for practice and who intend to emigrate there. The profession here, as at home, is vastly overcrowded, and a man coming out here must be prepared to bring enough money to keep himself for a year or so until he either obtains some appointment or his practice becomes lucrative. I can confidently state that every small village and town in Cape Colony and Natal is well supplied with medical men, and in the principal towns—such as Capetown, Johannesburg, and even in Buluwayo—the supply largely exceeds the demand. Everything here, as elsewhere, is obtained by local influence, and an outsider naturally has no chance against the colonial. This fact applies to every trade and profession out here. Locum tenencies and assistancies are extremely difficult to obtain as they are few and far between. Moreover, it is essential to have a good knowledge of the Dutch language, and besides there are always plenty of experienced men ready to take up these appointments, as I have found more than once to my cost. Fees certainly are higher, but then living costs at least double, even in Capetown, and in Johannesburg about treble the amount of that in England. An English practitioner can have no idea of the isolated rough life which one is forced to lead in the up-country districts, the centre of which may be 100 miles from the nearest railway station, and even there professional competition is frequently quite as keen as at home. The majority of medical men here are either of Scotch or German nationality. In view of the following facts I must advise men in quest of practice not to come here just now or they will be doomed to disappointment:—(1) Rinderpest, which by devastating the country must affect medical fees; (2) the unsettled relations between the Dutch and the English all over the colony; (3) the depression in the Transvaal; and (4) the uncertainty of the future of Rhodesia, all Stock Exchange reports notwithstanding. I am writing this letter chiefly to catch the eye of the junior members of our profession, and I shall feel sufficiently repaid if I am the means of preventing disappointment in the minds of those who think that South Africa is an El Dorado for the medical man as well as for the artizan."

IS CYCLING HEALTHY?

THE lengthy correspondence which has recently appeared in the columns of a contemporary has, as might have been expected, elicited a wonderful diversity of opinions. Some have nothing but good to say of the cycle; others record all sorts of aches, pains, and nervous affections coming on after a ride. One rider attributes these entirely to the use of the bicycle as apart from the tricycle owing to the unconscious strain involved in keeping the former upright. The plain truth seems to us to rest upon a very simple basis. Cycling is not good for everybody, and if abused is good for nobody. Within the last two years people of all ages have rushed into cycling in the most haphazard way. They have regarded neither age nor previous habits nor their physical condition. Small wonder then that many have found evil rather than good come from an exercise which inevitably demands a heavy expenditure both of nervous and muscular force. Probably just the same outcry would have arisen if the same class had suddenly taken to running or rowing or mountain climbing without any previous preparation. It is easy to preach moderation, but it must be remembered that moderation is a term varying with the individual, and everyone finds for himself how much he can do. With regard to the strain involved in keeping up a bicycle and keeping a look out it is probably no more than that involved in walking down the Strand without "cannoning" against others, but many of us have done the one from childhood while the other is but a newly-acquired accomplishment. There is no need to make a bicycle a very wheel of Ixion, especially with a "safety," for it is easy to get off and equally easy to remount; therefore the cry "You must go on or you will fall" seems to us to ignore the fact that we are reasoning animals.

THE RELATION OF SCARLET FEVER TO INSANITARY CONDITIONS.

THAT scarlet fever is infectious in a degree which probably varies in different years and outbreaks is a sufficiently obvious fact, but as to the exact channel by which infection is given off and conveyed there is not only considerable difference of opinion but also a lack of reliable evidence. That the disease is infectious during at least certain periods of the desquamative process is clear, but it is not altogether established whether infection is carried by the separated particles of cuticle or whether possibly desquamation is only associated in point of time with infection. Similarly with regard to the acute stage of the disease there are many who assert, upon what evidence it is not easy to ascertain, that the disease during this stage is not infectious; but, on the other hand, cases have been recorded which tend to show that even the pre-eruptive stage is not free from infective power. In a word, the evidence upon which beliefs are founded is somewhat scanty and unsatisfactory. Dr. Niven, the medical officer of health of Manchester, in his current annual report, while accepting the usually accredited means of spread, discusses as to how far scarlet fever may at times be disseminated by means of insanitary conditions, such, more especially, as defective privies and pails, which lead to soil pollution. Dr. Niven has collected information from a large number of houses which had been invaded by scarlet fever, and he finds that conditions of filth such as those referred to are more intimately associated with scarlet fever than they are, in Manchester at least, with diarrhœa and

Hosted by Google

enteric fever. He thinks that the frequent presence of albuminuria in scarlet fever, as also at times of nephritis, together with the not infrequent occurrence of diarrhœa and the swelling of the solitary and agminated glands of the intestine, all point to the infection of the disease being given off by the excreta, and that the pollution of the soil by this means may lead to the spread of the disease, a theory which would seem to receive some support from the seasonal prevalence of scarlet fever. Dr. Niven's views are, so far as we are aware, original, but they nevertheless deserve attention. Perhaps, if infection be thus given off by means of the excreta it might naturally be expected that a polluted water-supply will at times be found responsible for an outbreak; but again it may be that the micro-organisms of scarlet fever have but a very limited vitality in water.

THE BIOGRAPHY OF THOMAS WAKLEY.[1]

IN another column will be found a leading article suggested by our recently concluded Biography of the Founder of THE LANCET. We think it seemly, in view of the kindly eulogistic terms in which it is written, to state that it is from the pen of an old and valued contributor who was a member of the staff of THE LANCET when Mr. Wakley was the Editor and who was entrusted by Dr. James Wakley with the duty of writing the "In Memoriam" leading article on his father which appeared in THE LANCET of June 7th, 1862, page 605. It will be evident, therefore, to our readers that the writer, from his long personal knowledge of Thomas Wakley, is eminently qualified to render a tribute to his work and its influence on the medical profession. For this tribute we, the present Editors of THE LANCET, son and grandson respectively of its Founder, offer him our cordial thanks. Our gratitude is also due to the biographer, whose long and difficult task is (at all events, in its serial form) now concluded. We hope, however, to have an opportunity of expressing more adequately our sense of our indebtedness to him when the Biography is republished in book form.

"A CASE FOR THE MEDICAL COUNCIL."

SUCH is the heading of the report in the *Standard* of an inquest held on Dec. 24th by Dr. Wynn Westcott on the body of Bertram Lett, aged eleven years, the son of a gardener. The evidence showed that he was pushed downstairs on a Monday while playing at a neighbour's house. The leg became inflamed, and the boy's mother called in "Dr." Taylor, 240, Hoxton-street. On the Saturday "Dr." Taylor said the inflammation was spreading to the brain. On Sunday he called with another gentleman, whom the mother did not know. On the Monday the boy died. It transpired at the inquest that Taylor had attended the family for nine years, and that the mother believed he was a "qualified doctor." She paid him 3s. for five visits. The coroner's officer tendered an order for a post-mortem examination to Taylor, which he declined on the ground that he was not qualified. This officer said the name on the premises was Dr. Watts, who died eleven months since, but that Taylor lived there now. Mr. Hewitt Oliver, L.R.C.P. Lond., &c., deposed that he made the post-mortem examination and found septic pericarditis. "Dr." Taylor, on being examined, admitted having attended the deceased and family for eight or nine years. He said he was Dr. Hooper's assistant, having formerly been Dr. Watts's assistant. He attended people whose cases were not serious in Dr. Hooper's absence. This evidence was confirmed by Mr. Edmund Hooper, who said he had every reason to rely upon Taylor's treatment, and attributed his not being registered to the death of his father. The coroner asked Mr. Hooper why he did not remove "Dr. Watts's" name. Mr. Hooper said "he did not like to destroy it, it was so beautifully done." The coroner pointed out to the jury that the mother believed that Taylor was a "doctor." He intimated his intention to report the case to the General Medical Council. The jury added to their verdict of "Accidental Death" that Taylor ought not to have attended without disclosing the fact that he was unqualified. And they also said he was deserving of censure. The offence is a very real one, and it is amazing that any medical man should be found to associate himself as a principal with one who commits it.

"THE TRAINING OF NURSES IN RELATION TO REGISTRATION."

IN THE LANCET of Dec. 26th, 1896, we referred to a protest by certain members of the Royal British Nurses' Association against the registration of asylum attendants. Through the courtesy of Dr. Outterson Wood we are now in a position to place before our readers some facts relating to the other side of this question which must materially influence any decision upon it. We cannot do better than quote from Dr. Wood's letter. The attendants whose registration is desired are, he states, "thoroughly trained in their special branch of nursing." Furthermore, their qualifications are to include "three years' training in a hospital or asylum for the insane containing not less than forty beds, the certificate of the Medico-Psychological Association for Proficiency in Nursing (a certificate we may remark which entails a searching examination into the general principles of trained nursing), and a certificate of moral character." The education of these attendants is carried on under direct medical supervision. It is intended to register them as a distinct class of nurses and thus to afford the public a reliable guarantee of their proficiency. We are pleased to recognise in the course of training here explained those provisions for a sound, general, as well as special knowledge of nursing principles which, as we have already stated, are sufficient, and alone sufficient, to confer a title to registration.

CHILD LIFE DURING THE REIGN OF QUEEN VICTORIA.

AFTER a very fitting manner the National Society for the Prevention of Cruelty to Children proposes to celebrate the sixtieth anniversary of the Queen's accession. The same appropriateness appears in the place of meeting chosen for this purpose—namely, the Albert Hall, London. The object of this celebration will be to make public the conditions affecting the life and work of children at the beginning of Her Majesty's reign and to trace the legislative processes acting up till the present time which have brought order, decency, and happiness out of what was once a chaos of neglect and cruelty. The factory, the mine, the sea, the field, the street, the circus, and the home have each and all been invaded by the same terror, and have alike learned the healing power of a national will instructed and refined by the compassion of kindly feeling. It is a glory of this reign that during its continuance a work so eminent in its humanity should have been so far completed. None should feel more deeply than our Gracious Sovereign and the not forgotten Prince her Consort in all good deeds, were he present with us, the joy of having added so much happiness to human life. In spite of considerable difficulty arising from social or economic opposition legislation in regard to this matter has proved an efficient corrective, even when applied in cases which required the direct invasion of the home. We need hardly remind our readers that it is in cases of this

Hosted by Google

latter sort that the National Society for the Prevention of Cruelty to Children has been most active. Its increasing popularity may be taken as indicative of the manner and the spirit in which its difficult functions have been discharged. We would also note the fact that every other project of a like nature has been either aided in part or entirely carried out by the State Executive, while this is maintained solely by the provident liberality of voluntary contributors. It is only right, therefore, that the coming celebration should bring to the society, as it is hoped that it will, a fresh mandate and vote of confidence in the form of a marked increase in that liberality.

THE PURITY OF LAKE WINDERMERE.

IT is satisfactory to find that the statement made some weeks ago by a member of the Lancashire County Council that Lake Windermere was becoming a vast cesspool is shown by Dr. A. Hamilton, in a letter to the *Times* of the 29th ult., to be without foundation. Typhoid fever and diphtheria are practically, and have been for some time, unknown in the district, a result which may safely be attributed to the excellent attention which the local authorities give to sanitary requirements. Dr. Hamilton proceeds to show from a series of analyses made during the last twenty years that the quality of the water of the lake has not deteriorated. We note, however, that the analysis made in 1884 was not quite so satisfactory as that made in 1875, but the county analyst, in summing up his report on the results of analysis of samples of water taken from the lake in November last, says: "The water is now purer than in 1894 and in 1884 and almost as pure as in 1875." Of course the lake is liable to some pollution since there are three urban districts situated in its immediate neighbourhood, but it is evident that the authorities of these districts spare no pains to keep the lake clean, from the fact that they have recently spent £18,000 on purification works. The authorities are to be congratulated on taking these desirable measures to maintain the historic purity of the waters and Dr. Hamilton for having established a case against the allegation that more sewage is now being sent to the lake than hitherto or that the waters of the lake are less pure than formerly.

THE INDIAN FAMINE.

THE latest telegraphic intelligence from India gives a somewhat brighter prospect. The winter rains, although light at present, are becoming more general, and the extent as well as the severity of the famine will, it is hoped, be less grave than was at first anticipated. Bombay and Madras Presidencies may be considered safe; and the prospects for the North-West Provinces, Oudh, the Berars, and part of Bengal have improved, while there is still much anxiety as regards the Punjab. There are large tracts, however, where famine is being felt and where the outlook is a serious one. The food prices in Bengal, the Central Provinces, some parts of the North-West, and the Punjab are very high, and the prospects in Upper Burma are bad. Relief works have been opened at a large number of places, and vigorous efforts are, of course, being made to curtail or mitigate the extent and severity of the threatened disaster. The Anglo-Indian papers are naturally full of descriptions of the famine, of the distress and sufferings of the people, and of the increased sickness and mortality that are being caused by it, which are sad enough in all conscience to read, but far worse to witness, as those of our countrymen who have served in India under such circumstances know full well. There is no lack of energy in the strenuous efforts that are being made for the relief of the sufferers and in the organisation that has been devised for the distribution of food supplies to the native populations of the affected areas. The Indian Government and the governing classes of that country have to cope with enormous difficulties at the present time, but they have had previous experience to guide them and happily they always rise to the occasion.

THE committee of St. Martin's Town-hall have granted the free use of the large hall to the Charing-cross Hospital for Mr. Bancroft's reading of Charles Dickens's "Christmas Carol," on Friday, Jan. 22nd, in aid of that institution. Tickets can be obtained only at the hall or of the secretary at the hospital.

WE understand that a promise of £500 has been made to the University College Hospital conditional upon nine other persons promising the same amount, or £100 each per annum for five years.

THE LANCET
Special Sanitary Commission
ON THE
USE OF ANTISEPTICS IN FOOD.

THE increasing use of antiseptics as food preservatives demands attention. At present there exists no law providing for the suppression or control of the practice, unless it can be proved that the substance in question in the amount present is injurious to health, in which case it comes within the meaning of the present Food and Drugs Act. Otherwise it is futile to institute legal proceedings. The addition of a preservative to foods such as milk and butter, can hardly be regarded as fraud in the same sense as when their bulk is increased by the addition of water in the one case and foreign fat in the other, although on the other hand an antiseptic may be employed to preserve articles in incipient decomposition for some time, giving them the appearance of freshness and thus directly deceiving the purchaser in regard to their actual condition. It would, however, be obviously difficult to establish a clear case of this kind in court. The injuriousness of preservatives in food should afford a more satisfactory basis to proceed upon, but in regard to this, the most important aspect of the subject, we are confronted with the very serious difficulty of a strong conflict of opinion.

It was not to be expected that the Select Committee on Food Products Adulteration, which finished its labours and drew up a report in July last year, would offer any pronunciation upon these points, since not a single member of this committee could be properly described as a scientific authority, but on the other hand the committee consisted largely of traders and politicians. We have commented upon this fact before, which is one to be deplored. In connexion with a very important section of the subject, therefore, the committee were content to refer such matters to a court of reference of experts the creation of which they were led to recommend. They did not, however, leave the subject entirely alone, for in the report they remarked that although the adulteration of food with substances injurious to health had diminished greatly during recent years, and that whereas (in the old days of THE LANCET Commission) people were poisoned, now they are cheated; but at the same time the evidence taken in the proceedings showed that aniline dyes were employed very largely in colouring food-stuffs and that antiseptics were added to almost all perishable foods. Some of these dyes and preservatives, the committee went on to state, are said to be poisonous and their use would therefore appear to be prohibited by Section 3 of the Act of 1875. Again, "your committee understand that it would be difficult to prove that some agents, colouring, and antiseptics are injurious to health, but the opinion has been expressed that some limits to their use should be imposed. Your committee are informed that in France the sale of any article to which antiseptics have been added is absolutely prohibited, and a similar course appears to have been taken in Germany, Italy, Spain, Brazil, and the Argentine Republic. Your committee

Hosted by Google

think the matter is one which deserves further investigation by recognised scientific authorities with the view to the expression of an opinion that would be regarded as authoritative." In another section of the report relating to the proposed functions of the new court of reference there occurs the sentence that "among the matters referred to (for the consideration of this court) may be mentioned such questions as the wholesomeness of ingredients used in the preparation of food, and the legitimacy of the use of colouring agents and preservatives."

Finally, in regard to the attempts which have been made to bring legislation to bear upon those who have employed antiseptics in articles of food, it is interesting to notice that the Local Government Board said, when appealed to upon this question, that "the question is one which the board have no authority to decide" and referred to note "d" appended to the form of certificate provided in the Act, according to which the analyst may say whether, in his opinion, the mixture was for the purpose of preserving the article and whether it was excessive in quantity. Allusion was further made to the report of the Local Government Board 1890–91, in which it was stated that "there is no doubt that boric acid if taken in large quantities would be injurious to health, but we have not sufficient information to show whether such minute amounts as are generally added as preservatives could be regarded as having that effect, and more exact information is wanted before it can be decided whether a process which *primâ facie* may be regarded as intended to prevent the loss of valuable foods must be held to be prohibited by law."

It is obvious from all this that the English law as it stands at present does not prohibit the use of preservatives so long as they are not shown to be injurious to health. This being so, it is futile to institute proceedings against the vendors of articles of food so treated without some evidence of this kind. Much public time and money has, however, been wasted over this matter in proceedings which have been instituted chiefly on the ground that the substance employed has been injurious to health. Even in the majority of these cases, if not in all, this argument has generally failed to convince the magistrate in view of the sharp conflict of views presented before him upon this subject in the evidence of expert witnesses. It may be here remarked that unless he is a duly qualified medical man the public analyst cannot be regarded as competent to give an opinion as to whether the preservative in question is injurious to health or not. His duty, we take it, has ceased under the present administration when he has stated in his certificate the fact of the article being preserved and if possible the quantity of the preservative, but of course if the use of certain preservatives should come to be entirely prohibited by law then he could pronounce definitely and decidedly against that food being fit for consumption which has proved to contain a preservative scheduled by the law as objectionable. It is on the question of injury to health upon which it is alone possible, it seems to us, to demand the aid of legislation, and no approach in this direction can be made until very definite evidence is forthcoming of actual injury to health having been caused by the consumption of articles of food preserved with those antiseptics which are now so commonly met with. At present there is very little evidence of experience available that any serious injury has been caused to health by the use of antiseptics in food, but it is possible that in certain obscure cases of illness the chances of injury to health by this means may have been overlooked. Cases, it is true, have been reported from time to time, but not one has evinced any grave importance, while in some instances the arguments in favour of a preservative agent having done the mischief have not been as conclusive as might be desired. There was apparently a serious case reported comparatively recently by the medical officer of health to the East Kent Joint Committee in which milk that had been twice treated with borax, or its basis, boric acid, would seem to have led to a serious and sudden outbreak of illness. On considering the facts of the case, however, it is by no means clear that the injury was caused by the preservative in question. The symptoms pointed to ptomaine poisoning rather than to the effects of borax. This fact, however, may even afford an indirect argument against the use of preservatives, since possibly the unwholesomeness of the food may be covered by means of a preservative. In the notes of this case it is remarked by the writer, Dr. M. K. Robinson of Dover, that the results indicate the necessity for precautions being taken when prescribing this drug for medicinal purposes, and also in respect to its use as a food preservative. On the contrary, it is well known that considerable amounts of borax are frequently prescribed and are found to be borne with impunity.

The extreme importance of this subject has appealed to us for a long time, especially with a view to ascertaining whether legislation on this subject was in the first place called for, and in the second whether it could be made practicable. The aid of legislation would, of course, be called in either to restrict the practice altogether, or else, recognising its necessity, to place it under some control. In any case it is very undesirable that the legislative use of drugs in food for preserving purposes should be left without admonition in the hands of those who are quite ignorant of the nature of these drugs. The vendors' chief object in employing antiseptics is for the purposes of preserving for his own gain, and it is conceivable that he may be tempted to use a far greater amount than is necessary, so as to be quite certain of securing the food against a change which would render it unsaleable.

The question to be decided, therefore, is as to how far the use of preservatives can be held to be objectionable on hygienic grounds, and this, as the Food Products Committee puts it, is a matter "which deserves further investigation by recognised scientific authorities, with a view to the expression of an opinion that would be regarded as authoritative." It is obvious that this expression of opinion must rest entirely on the evidence and experience of medical men of recognised authority. The main purpose of the present article is to put before our readers representative views of members of the profession in regard to this important subject. The opinions expressed in the letters printed below were kindly furnished to us in response to the following letter.

THE LANCET Offices, Strand, W.C.

DEAR SIR,—We venture to bring under your notice the following facts regarding a very important subject and shall be greatly obliged for any information or advice which you can give us.

During the last few years attempts which have very generally proved abortive have been made at great expense to the public authorities to obtain convictions under the Food and Drugs Act in connexion with the use of certain antiseptics in the preserving of foods, beverages, &c. These cases have generally broken down because it has been held that articles of food so treated are not injurious to health in view of the small quantity of the preservative employed. A very definite pronouncement is wanted on this point and would be particularly opportune just now since the use of preservatives in food and various preparations (very often intended for the use of invalids and infants) is, there is reason to believe, largely on the increase. Not long ago a case was heard in which a British wine was proved to contain two or three grains of salicylic acid per pint. The prosecution failed because there was no evidence forthcoming as to the injuriousness of that small quantity. Milk and butter constantly contain boric acid and no conviction has ever been obtained on the score that the preservative used had any prejudicial effect upon health.

Is the presence of small quantities of salicylic, boric, benzoic acids or "formalin" in food in sufficient quantities to preserve it injurious to health? Should the use of antiseptics for this purpose be forbidden by law altogether, or should legislation be brought to bear on the restriction of the amount, or should the law insist that when preservatives are used the fact should be stated on the label?

We understand that public analysts are most anxious to have definite medical opinion on these points and we desire to help them to obtain such an opinion. We shall be deeply indebted to you if you will be so kind as to give us the benefit of your knowledge on the subject.

We are, Dear Sir, yours faithfully,

THE EDITORS OF THE LANCET.

Sir HENRY THOMPSON wrote:—"I have long held the opinion that the practice of adding antiseptic agents to articles of food which are daily and habitually consumed by individuals of all ages, including even infants in arms, is a most undesirable practice. I cannot produce evidence to prove that any one of these agents has given rise to deleterious action on the persons taking them. So great a number of concomitant circumstances

Hosted by Google

exist in connexion with the diet and management of people at large that the attempt to isolate the precise influence of the antiseptic drug must almost certainly be impossible. Some five or six years ago I was especially consulted by the municipal authorities of Kensington relative to this subject and strongly advised their limiting the employment of antiseptics on the part of dairymen and others, who, it appears, were using them freely, and I laid special stress on the undesirability of feeding very young children on milk thus 'preserved.' But on general principles I entertain a very strong objection to the *dietetic* use of any drugs; and thus I object greatly to the large general use of mineral waters containing them, as they all necessarily do, to a larger or less extent. I am not speaking of their medicinal use or of aperient waters, but of *drinking* waters containing often considerable quantities of mineral salts, such as carbonate of lime, soda, and magnesia. I infinitely prefer for the general consumer the use of distilled water aerated. It is, in fact, the most perfect drink for habitual use, especially amongst dense populations, where local wells or other sources are liable to become contaminated. Where the use of alkaline carbonates is necessary or desirable it is easy to take a known quantity, and at a suitable season of the day, which is certainly not generally at the time of taking food, when such mineral waters are mostly consumed. Certainly I am of opinion that in every case of articles offered for public sale containing an antiseptic agent the name and quantity of the material employed, and thus added, should be stated by label when possible; or at all events should be expressed on a paper, setting forth also the maker's or vendor's name."

Dr. PAVY wrote:—"Pray excuse this tardy reply to your letter regarding antiseptics and food, but I have not been able to give thought to the matter before. Because no tangible evidence is forthcoming of injury to health arising from the employment of antiseptics in small quantities for the preservation of articles of food I do not consider that our knowledge can be regarded as sufficiently extended and complete upon the point to permit its being absolutely taken for granted that no injury is producible. By the use of antiseptics it is the vendor and not the consumer that is benefited. An article that may have been kept for some time is made to present the appearance of one in the fresh state. To countenance this without the distinction being made known would be clearly unjust to the purveyor of the fresh article and calculated to lead to a relaxation of general effort to supply in the fresh state. Encouragement will also be afforded to insufficient attention being given in the fabrication of an article to secure self-maintaining goodness. Reference, for instance, is made in your letter to the addition of salicylic acid to British wine. A good and properly made wine does not require such addition, and by its agency inferiority may be covered and an unfair semblance of quality which does not exist be given. The same remark applies to beer, and an article in the preparation of which care is bestowed so as to give it self-preserving power is placed on a level with one that would become unsound on keeping if it were not for the antiseptic used. Justice, I consider, all round demands that antiseptics should not be allowed to be used without the fact of their employment being made evident so that the purchaser may know the nature of what is supplied to him. With respect to the question of restricting by legislation the amounts of antiseptics I consider it would be unwise for the legislature to incur such a responsibility. If it defined the amount that might be used it would be establishing, as it were, by legislation that no harm can accrue from the employment of such an amount. The onus, I am of opinion, should be thrown upon the vendor. He should not only reveal the fact of the presence of an antiseptic but at the same time should be required to specify its nature and amount. In other words, the onus should be made to rest upon the vendor with respect to the addition both as regards nature and amount being injurious or not to health. At the same time he should be made liable to prosecution for any deviation given regarding the antiseptic introduced. With the public interest thus safeguarded I think advantage might be taken of the power of antiseptics in preserving articles of food."

Dr. F. J. ALLEN, Professor of Physiology in Mason College, Birmingham, wrote:—"The substances used as antiseptics in food may be classed under two headings:—(1) those that are foreign to the animal organism, and (2) those that are unusual, but not foreign, since they are occasional constituents of normal food. Among the latter may be named benzoic and salicylic acids, which we take in minute quantities in vegetable foods, and which a healthy body can dispose of without disturbance of its functions. On the other hand, boric acid and its compounds are quite foreign to the animal body and their presence must necessitate a departure from the normal chemistry of life. The departure may be expected to consist partly in the formation of inert compounds of boric acid with calcium and magnesium (perhaps also iron), and the consequent removal of these indispensable metals from the economy. Whatever antiseptic may be used, it should be remembered that in order to obtain its due effect there must be enough present to exert a decided influence on photoplasmic activity. This effect can hardly be expected to be beneficial to the tissues of the alimentary canal. Even the disinfection of the contents of the canal is a doubtful blessing in most cases, because the beneficial organisms are thereby destroyed. However harmless an occasional dose of boric acid (or one of its compounds) may be, it is evident that the case may be different when nearly every article of diet contains it. If we take boric compounds with our bacon, sausages, fish, butcher's meat, preserved meat, milk, cream, butter, preserved fruits, jams, beer, cider, and wine, the result may be daily accumulation quite sufficient to produce a considerable constitutional disturbance and a gradual lowering of the standard of health. I am of opinion that if any article intended for food contains any added antiseptic the fact and the nature of the antiseptic should be required by law to be distinctly announced at the time of sale. The name antiseptic should not, of course, include common salt, nitre, spices, or wood-smoke."

Dr. G. SIMS WOODHEAD wrote:—"It is a somewhat difficult matter to give a very definite opinion on the points raised in your letter. In the first place I hold that the onus of proof rests on those who use those preservative substances in the preparation and preservation of food stuffs. As a matter of fact, we know that the question of idiosyncracy or personal constitution enters very largely into the question as to whether the substances used—salicylic acid, boric acid, and the like—are dangerous; and what may be comparatively harmless in 99 cases out of 100 may be exceedingly harmful in the hundredth case. Then it must also be borne in mind that what may be comparatively harmless when given in a single dose, or for a very short period, may have very serious effects if continued over a lengthened period, and the physiological effects of multiple doses, especially if the substance have any 'cumulative' action, may be exceedingly harmful. Then, again, we do not know as yet what effects certain of these drugs—formalin, for example, which acts very directly on albuminoid substances—may have upon food stuffs, especially as regards their actual digestibility, and until these points are settled it should certainly be illegal to add them. One would have thought that the taste given to foods by the addition of certain of these substances would be sufficient to exclude their use, but unfortunately this is not the case. These substances, whatever they are, are adulterants, and the milk or other foods to which they are added are to the extent of their addition adulterated. If it can be proved that such substances can be used safely then let permission be specially granted, but it is certainly inadvisable to allow anyone to use substances to preserve his wares simply because he thinks they are innocuous. The last point to be considered is that allowing the use of such preservatives is a direct incentive to the distribution of 'doctored' articles of food. Taking milk as an example, it is possible, as we know, by the use of chalk and other substances, to render sour milk saleable as fresh milk, and it is imaginable that by the addition of chalk and, say, formalin that such milk may remain saleable for some time after it has been 'doctored'; but no one would convince anyone who has studied the question of milk as a food for children or would contend that such milk is fit for food for any but the most robust digestion. The same theory should be carried into every question connected with food-supply. Let food be sold as pure, fresh food, free from chemicals of any kind, or if chemicals are used make it illegal to use them unless a full description of their nature and quantity be made known by means of a label or placard printed in large type."

The late Sir BENJAMIN WARD RICHARDSON wrote:—"I have read your letter carefully respecting the use of antiseptics in foods, and my opinion is that they, in foods, are not only necessary at this moment, but that when used

Hosted by Google

in proper form and quantity they are perfectly correct—that is to say, they cause no injury whatever to the consumers. There ought, therefore, to be a licence given, permitting, in every case where it is necessary to preserve, a certain fixed and not dangerous quantity of an antiseptic; and I think it ought to be stated on the label what that antiseptic may be and what is the quantity of it used."

Dr. T. LAUDER BRUNTON wrote:—"I think one must draw a sharp distinction between substances added to foods, condiments, or other articles intended for consumption for the purpose of simply increasing the profit of the vendors, and such substances as are added for the purpose of preserving perishable articles from the changes which would otherwise take place in them. As an example of substances added for the mere purpose of increasing the sale of an article, I may instance salts of copper added to tinned peas in order to give them a greener and fresher colour. The question of copper as an agent for this purpose has been a subject of much discussion, some holding that the copper is not injurious and others that it is; but whether it be so or not, I think that with such conflicting evidence the purchaser ought to have a chance of taking such risk as there might be, or avoiding it at his discretion, by having a clear statement upon every tin of peas that they contain copper if copper has been added, and that peas to which copper has been added, and which are not said to contain copper, ought to be regarded as adulterated and the vendors should be liable to a fine.

"The same rule ought, I think, to apply to all substances about which there may be the least doubt and the use of which is not actually prohibited by law, such as the use of alum in baking-powder, &c. In regard to substances which are simply added for the purpose of preventing such changes in perishable articles as would naturally occur without their addition, I think one must remember that poisons are actually formed from foods by their spontaneous decomposition, and that foods which might be perfectly good and harmless at the time they were sold might be allowed by the purchaser to remain lying in a warm place for such a time that spontaneous alterations might occur in them, and illness, or even death, might result from their consumption. This, of course, we know to be the case with meat, but even with butter we know such changes may occur as will render it rancid, and the fatty acids which are then present may act as violent irritants and produce severe indigestion. Similar changes may occur in other articles of food, and the question really comes to be whether the acids, salicylic, boric, or benzoic, which are added to prevent decomposition are likely to be more injurious to health than the natural products of decomposition which would be formed were the preservative not added. My own belief is that the preservative acids are likely to be considerably less injurious to health than the natural products of decomposition, but this is a point upon which considerable divergence of opinion might occur, and I think that here also the purchaser should be allowed the chance of judging for himself, and that where any preservative is added the fact of its addition and the amount added ought to be stated by the vendor. This would enable the purchaser either to avoid the article altogether, if he thought that it was likely to harm him, or to avoid any risk such as might occur from his taking such a quantity of the article as would contain an injurious amount of the preservative. For example, in the case of British wines, which contain two or three grains of salicylic acid per pint, this quantity could not do the person who consumed it any harm; but if he were to get through a dozen pints in the course of a hot summer's day the quantity of salicylic acid might possibly be then enough to harm him. In answer to your questions, then, I should say that the use of antiseptics should not be forbidden by law. Secondly, it is doubtful whether legislation should be brought to bear upon the restriction of the amount, because this will probably be settled by the quantity actually necessary to prevent decomposition. The makers of an article will in all probability use the minimum amount of antiseptic sufficient for their purpose, and legislation in regard to the amount might be simply meddlesome and injurious. Thirdly, it ought to be most stringently insisted upon by law that whenever preservatives are used the fact should be stated on the label as well as the amount used."

Sir WILLIAM ROBERTS wrote:—"I take it that there is really no reliable information available on the subjects embraced in your circular, and I doubt very much whether the opinions of medical practitioners on the points in question are of any value and they might be very misleading. What is wanted is an inquiry, and it would be a very long and difficult one."

Dr. W. D. HALLIBURTON wrote:—"I regard your letter as one on a subject of great importance, though I regret I am not able to give you much information from my own experience on this matter. On general *a priori* grounds it can hardly be doubted that the continued use of even small quantities of antiseptics is injurious, though it is difficult to put one's finger on any definite symptoms or recall any case in which it would be positively stated that the ill-health is due with certainty to the use of foods uncontaminated in the way you describe. On the other hand, I and all of us are continually taking such food (especially milk treated with boric acid) without any appreciably bad results. Professor Allen, Mason College (Physiological Department), Birmingham, was speaking to me about boric acid in milk the other day and said he was acquainted with cases of ill health in children due to its use. He told me the antiseptic prevented the proper action of re-union, which appears to be essential in the digestion of milk. I fancy it must want rather a large amount of boric acid, however, to prevent rennet action, as in the west country essence of rennet is generally kept sweet with this substance."

Dr. J. B. BRADBURY (Cambridge) wrote:—"No case has come under my notice in which I thought small quantities of antiseptics used in the preservation of foods, beverages, &c., have been prejudicial to health, and I am disposed to think that the presence of small quantities of salicylic, boric, or benzoic acids, in sufficient quantities to preserve it is not injurious to health. In my opinion it is not necessary to forbid by law the use of antiseptics altogether, but the amount should either be restricted or the fact of preservatives having been used should be stated on the label."

Dr. WHITELEGGE wrote:—"I am scarcely prepared to speak positively upon this matter. I have no doubt that large proportions of such antiseptics are harmful, but I do not know enough of the facts to affirm that there is no antiseptic which could be employed in a proportion so small as to be harmless.

"It seems clear to me that the law ought to insist upon a plain statement on the label if any 'preservative' or antiseptic, or, indeed, foreign material of any kind, be added."

As will be seen from these communications there is considerable diversity of opinion as to whether antiseptics in the quantities used for preserving food are injurious to health, and also whether legislation could satisfactorily deal with the subject, although on the whole the conclusion appears to be not altogether unfavourable to the use of preservatives with certain restrictions. The majority agree in one thing, and that is that should the practice be tolerated it should be placed under some control, so that, for instance, where the addition of antiseptics is practised it should be notified to the purchaser. Very few of our correspondents, it is important to note, are able to quote cases within their experience of injury to health having been caused by preservatives in food.

Although, to sum up, it would be difficult for the legislature to lay down hard and fast lines as to the quantity of antiseptic permissible, yet there seems no reason why the purchaser should not be entitled to demand an article free from certain preservative which could be scheduled. We certainly think that if the practice is to be permitted at all it should be subjected to control in regard to the amount and kind of preservative to be used, but it is difficult to see how legislation regulating the precise quantity of preservative could be made practicable. If legislation is to step in at all it must be either to allow or not to allow the use of preservatives, or certain of them, in food, and in the event of the former course being decided upon it should be insisted that the vendor should notify by label or in some other way the fact of a food being so preserved. At the same time, it is desirable that the public should be able to demand an article free from preservatives just as now under pain of penalty they can demand pure coffee unmixed with chicory. Similarly when a purchaser asks for fresh beef he does not expect to get beef preserved with salt, or pickled pork when he asks for fresh pork, tinned fruit for fresh fruit, and so on. There are certain preservatives in common daily use which nobody can suppose for a moment to be injurious; such are, for instance, salt, sugar, acetic acid, wood-smoke, &c.; but these, it is

Hosted by Google

argued, with of course the exception of the last-named, are not foreign to the animal organism. (The "curing" property of wood-smoke, it should be remarked, is dependent upon the presence of creasote bodies). It is probably, after all, merely a question of degree of preserving power; boracic acid, salicylic acid, and formalin are infinitely more powerful antiseptics than salt or sugar, and consequently to effect a certain preserving property may be used in infinitely smaller quantities.

It seems to us that in some cases preservatives may have their legitimate use, as unquestionably there would be much good and valuable food lost and wasted, especially in the hot summer months, if there were no easy and convenient means of preserving it against change. Unfortunately, where there is a legitimate use for a thing or method abuse is bound to creep in. It is the possibility of this abuse against which legislation should be directed.

MEDICAL ADVERTISEMENTS TAKEN FROM OLD NORWICH NEWSPAPERS.

BY CHARLES WILLIAMS, F.R.C.S. EDIN.

THE newspapers of the latter portion of the seventeenth century contain many extraordinary advertisements respecting the healing art. The following curious examples are taken from Norwich newspapers of that period. Not only were they inserted by quacks and barbers, but by surgeons and apothecaries who did not consider it derogatory to advertise the power of their drugs and the marvellous skill they possessed in being able to cure, without question, every possible complaint that man is subject to. Women did not despise the same means of making known their medical and surgical capacity. So far back as 1390 they appear to have dabbled with medicine; one of the ordinances issued by the barbers of London authorises the masters to make scrutiny, not only of men, but of women undertaking cures or practising the art of surgery. On the other hand we see in 1568 the Bishop of Norwich licensing Cecily Baldrye of Great Yarmouth to practise the art of chirurgery, and the widow of Nicholas Colman was licensed in 1596 by the Privy Council "to minister her best skill and cunning to women, children, &c.," and this practice was also recognised by the Mayor of Norwich, who paid Frances Bush 5*s.* towards the cure of Goodwife Woolsey (1673), and in the register of St. Benedict is an entry under date 1666, "Paid to Mrs. Scarfe for setting of Mary Usher her leg, 10*s.*" And now in the nineteenth century we find history repeating itself, and women again intermeddling in matters surgical.

Mrs. Taylor's advertisement.—"This is to give notice that the Widow of the late Dr. Taylor, deceased, still continues her Practice of Physick, and has by the Blessing of God lately cured several of the Rheumatism, Dropsie, Scurvey, and several other diseases incident to human bodies. She has also an infallible Remedy for the Stone and Gravel which gives immediate Relief to the Patient in less than an hour after taken. She likewise bleeds and gives judgment on Urin."—*Cosgrove's Gazette*, 1710.

Mrs. Dimes's advertisement.—"The Original Stone and Gravel Pill being a medicine so well known and approved of by all people who have try'd it, to be the only Remedy to cure the Dropsie, Wind, Collick, Scurvey, and Rheumatism, which by God's blessing it never faileth to perform, if curable, in both sexes and of all ages tho' never so far gone (without let of time), is made and sold only by me, Mary Dimes, Wid., at my house near St. Simon's Church, Norwich."—*Ibid.*, 1710.

"John Bennett, near the 3 Cranes in the Cathedral Close in Norwich, Chirurgeon and Student in Physick, cures after a new, speedy, and safe method the lues venerea, or French disease, of the longest date with the worst of symptoms, without let to business, as is well known to some hundreds, after given over by others, and has a large Testimony allowed to show the Incredulous. A clap he cures in a few days and desires nothing for his pains; cures the Asthma, Catarrh, Rheumatism, Green Sickness, Dropsies to admiration, Feavers, any sort of Agues in a few hours, inveterate pains, Rickets in children even to a wonder, cures Tumors, Wounds, Old Ulcers, Cancerated Breasts, Dislocations, Fractures, Ruptures in any part of the Bodies of Women, Children or Men, if so born, or of 30 or 40 years' continuance (and where all Remedies hereunto has failed), as more than 500 can testifie since 8 years past, and 50 more within 3 months. He cures many other diseases gratis and directs the poor in the cure of any disease gratis. His being gone to Sea again in the Navy is as false as his being dead last year when in Spain."—*Cosgrove's Gazette*, June 10th, 1710.

Sir William Read, Kt.—"Notice is hereby given that Sir William Read, Kt., Her Majesty's Principal Oculist and Operator of the Eyes, and in that Quality Sworn Servant in Ordinary, as he was to King William. His occasions call him to Norwich, where he has several patients to attend, and in the adjacent Parts, So he will be to be advised withal for some time at Mr. George Bussey's at The Angel, in Norwich Market Place, from the 25th of October, where all people shall be served with honourable and fair Practice. As he has made demonstrations among you several times after 35 years' Experience, which is beyond Pretenders, especially to cure of the eyes, who know nothing of the matter more that to trick people out of their money, for these bold pretenders are as dark of their understanding as they leave most of their patients of their sights after they have tried practice upon them to the ruin of most they undertake. Note.—Sir William cures Hare-lips and Wry Necks, tho' never so deformed, and prevents Cancers and Catarrs in the beginning, and takes off all sorts of Wenns and Tumors."—*Cosgrove's Gazette*, October, 1710.

The learned Knight was "hindered in his intention of coming on account of having to attend to some persons of quality in distempers relating to the eyes." However, in a short time there appears the following announcement:—

"This is to satisfie the Publick that Sir William Read, Kt., Her Majesty's Principal Oculist and Operator for the eyes, and in that quality Sworn Servant in Ordinary, does design (with God's assistance) to be at Mr. Bussey's, at the Angel in the city of Norwich from the 1st of January for some months, where the Poor shall have his advice gratis and others kindly used; and all persons blind of Cataracts shall pay for their cures after the success of his operations. He thinks it necessary to give this publication, that the City and County may not be imposed upon by Pretenders, who are as much strangers to the practical part of the Eyes as they are to the persons they so boldly attempt their cures upon."—*Cosgrove's Gazette*, Dec., 1710.

John Pell, Lythotomist.—"Lythotomy being supposed here as distinct from Surgery, and I being thought one of those Surgeons that do not cut for the stone, do find myself obliged from that consideration as well as from the Persuasion of my Friends to make this Public declaration for the benefit of miserable Mankind, that all who are afflicted with the stone may by my cutting them (and by the Divine Blessing) be cured of the same, I having had the good fortune to be instructed in that dangerous and difficult operation of Cutting for the Stone by the Great Mr. Salter of London, the most Ingenious and successful lythotomist now in England. Note.—All that are truly poor may have advice and be cut gratis by me, John Pell."—*Cosgrove's Gazette*, July, 1710.

Dean Prideaux, who suffered from stone, evidently had no great opinion of John Pell, for he "sent for the famous lithotomist, Mr. Salter, from London, to perform the operation, which he did with great dexterity, drawing out the stone, which was the size and shape of a sheep's kidney, in less than three minutes' time." The dean recovered and lived fourteen years, but nearly lost his life in the cure.

Mrs. Hacon's advertisement.—"All persons indebted to Hubert Hacon, Surgeon, lately deceased, are hereby desired to pay in all their respective debts forthwith to the Widow, his sole Executrix, or they will be sued for the same. She lives near the Cardinal's Cap in St. Swithin's and cuts hair for either Gentlemen or Ladies to the greatest Nicety. She lets blood very finely and to the poor for threepence. She has also an excellent Sear-cloth for pains and strains which she sells for ninepence a quarter; and for the Rheumatisme she has the same infallible remedies which the Doctor himself always made use of."—*Cosgrove's Gazette*, 1716.

Mr. John Harmer's denunciation.—"Whereas one Mr. Charles Haynes, a Stranger, has been in this City a considerable time as a Man Midwife, but having little practice here in that way has that charitable disposition of mind (towards himself) as to offer to the Court of Guardians, as advertised in last week's paper, to deliver the poor gratis. Now I, John Harmer, who have received Money of the Court of Guardians for the same work and am a Native of this City, and have performed several acts of Charity here in the Art of Surgery,

Hosted by Google

should be ashamed to be outdone by a Stranger in those acts; therefore, I give public Notice that I will attend and assist Gratis in this necessary work all such poor women as are not able to pay.—Witness my Hand, John Harmer, Surgeon, St. Clement's, Norwich.

"N.B.—As Mr. Haynes is a young man and a Batcheler I advise him to marry as a necessary qualification, for I believe it was never known (neither is it decent) for a Batcheler to perform such operations."—*Cosgrove's Gazette*, 1729.

Mr. John Harmer was a well known surgeon and lithotomist in this city. He was evidently much nettled with the conduct of the young man Haynes. On the other hand Harmer was, like most *medici*, very fond of seeing his name in print, as the following notices, taken from the *Norwich Gazette* of that period, amply prove:—

"On Sunday last was cut for the stone by Mr. John Harmer, Surgeon in this City, Peter Riggs, a lad about 17 years of age, and was extracted from him (to the great surprise of the Spectators) an iron shuttle-spire 4 inches long. He had some time before a stoppage, endeavoured to relieve himself with a shuttle-spire, let it drop into the passage through which it conveyed itself into the bladder, and occasioned the same symptoms as a stone. He underwent the operation and at the same time concealed the cause thereof. He is in a fair way of recovery."—*Norwich Gazette*, Sept. 22nd, 1744.

"On Sunday last was cut for the stone by Mr. John Harmer, John Howse, gardener, from Porland, aged 49, from whom he extracted a stone of a prodigious magnitude, measuring 12 inches one way and 8 the other, and weighed upwards of 14 ounces and a half, and is said to be the largest ever extracted from any one person who recovered the operation, as this man is likely to do, he not having yet had one bad symptom. In my next I shall insert a further account of this operation, in which the Publick shall be informed whether the patient be living or dead. The same gentleman about three weeks since cut a kinsman of the above-named person and extracted a very large stone from him who is recovered."—June 7th, 1746.

"John Howse, the Gardener who, as mentioned in my last, had the large stone (which weighed upwards of 14½ ounces) extracted from him is in a fair way of recovery and judged to be out of danger. The above Mr. Harmer has cut for the stone upwards of 170 persons, and that with as much success as any man living, but never extracted one so large before."—June 14th, 1746.

This case still remains on record as the largest stone removed by lithotomy from which the person recovered. Howse lived five years afterwards. The stone is preserved in the museum of the Norfolk and Norwich Hospital.

"On Monday last Mr. John Harmer, Surgeon, extracted from the bladder of James Ruston, in St. Mary's parish, two stones, each of them about the size of a pullet's egg, and notwithstanding its being the different season of the year for performing this operation in, the man is in a fair way of recovery, as is the man who had the large stone of 14½ ounces extracted from him some weeks since by the same gentleman."—July 5th, 1746.

Daniel Nelson, Loddon.—Dr. Palmer, of Loddon, being lately deceased, who used the art of Midwifery, having served his apprenticeship some years since with the late famous Dr. Havers, of Stoke Holy Cross, by Norwich, well known by his skill in that practice. ..... I Daniel Nelson, Surgeon in Loddon aforesaid, having faithfully served as an apprentice with the said Dr. Havers, and having by pains and study as well as Anatomical courses made himself Master of the said Art so necessary for all Women Labouring under any difficulties in child bearing, he advertises this that he is ready at any time when wanted, at the most reasonable charges. N.B.—He undertakes to cure all Lunaticks if curable."—*Cosgrove's Magazine*, 1732.

This advertisement is exceedingly interesting because of the mention of the name of Dr. Havers, who was the Rev. Thomas Havers, but better known by the former title, to whom there is a monument on the outside of the south wall of Stoke Holy Cross Church, and on which he is described as being learned in theology, physics, surgery, and lithotomy, as well as "pauperibus et ægrotis semper amicus." The designs of various surgical instruments are carved in stone at the bottom of the inscription. He appears to have had a considerable reputation as a surgeon, and one is surprised that with his ability and love for the profession he did not leave Stoke and seek a larger scope for his talents in Norwich. In 1683, at the age of twenty-four years, he was presented by the Duke of Norfolk to the living of Framingham Earl, from which he retired in 1701 to devote his time and energies to the practice of medicine and surgery at Stoke Holy Cross, the village he never left, but ended his days in in 1719. He was in the habit of taking pupils and teaching them surgery and midwifery, as is exemplified in Daniel Nelson's advertisement. In his will, dated 1719, he left £20 to the poor of Stoke and his "instruments of chirurgery to his nephew, Robert Bransby of Hapton Hall, Norfolk." This Robert Bransby, whose aunt Havers had married, was a surgeon. He subsequently removed to Shottesham, and there died in 1748. His daughter Elizabeth became the wife of Benjamin Gooch, the most celebrated surgeon of his day, who in 1771 greatly assisted to establish the Norfolk and Norwich Hospital, his patron, William Fellowes of Shottesham Hall, distinguished by his friends as the "man of Shottesham" from his resemblance to Pope's "Man of Ross," being the actual founder of that institution. This gentleman some years previously had recognised the value and advantage of such places, and had erected at his own expense in Shottesham a cottage hospital for the benefit of the poor in that neighbourhood. With this Gooch was for many years connected as surgeon. It gave him the opportunity of acquiring an amount of surgical practice which subsequently enabled him to write three very interesting volumes of "Cases and Observations in Surgery." This is the first instance of the existence of a village hospital in England; the next was founded eighty-eight years later at Cranleigh in Surrey in 1859.

Benjamin Gooch's only daughter Sarah was engaged to Lord Chancellor Thurlow. Lord Campbell, in his "Lives of the Chancellors," informs us that "she was afraid of him and would not have him." Ultimately she was married to Dr. D'Urban, who had succeeded Gooch at Shottesham, and became the mother of General Sir William D'Urban. Sir Astley Cooper's father was the Rev. Dr. Samuel Cooper, rector of Shottesham. He married a daughter of James Bransby, second cousin to Mrs. Gooch. In this way the families of Bransby, Havers, Gooch, and Cooper became intimately connected. Dr. Cooper's eldest son was Bransby Cooper, M.P. for Gloucester.

THE PLAGUE IN BOMBAY.

THE latest intelligence regarding the plague epidemic in Bombay is very far from satisfactory. The number of cases is increasing and the disease is extending; it has advanced to the suburbs and also to Bandora. According to a telegram of the 28th ult., through Reuter's agency, the health of the Europeans, however, is very satisfactory, no deaths having been recorded among them from any cause during the past week. Up to the present time the plague statistics give 2004 cases and 1494 deaths, but it is believed that these numbers do not really include all the cases that have actually occurred. Since the outbreak of the disease in Bombay there has been an enormous exodus of the population, which still continues. The week's mortality up to Dec. 28th from all diseases was 1416, which is in excess of all previous records for Bombay. The estimated mortality, calculated at the ratio of the reduced population, reaches the very high figure of 109 per 1000. A later telegram from Bombay of the 29th ult. states that 177 cases of plague with 130 deaths have been registered in that city in the past two days. The local press, it is stated, animadvert strongly upon the apathy displayed by the special plague committees and the members of the corporation. They also condemn the revoking of the regulations regarding segregation under the pressure of the sanctity of caste, and warn the people of the possibility of a military *régime*. The experience of Hong-Kong, it is urged, is in store for Bombay unless things take an unexpected turn. Cases of plague have also been reported as having occurred at Poona and Karrachi.

The great difficulty in making a successful effort to stamp out epidemic diseases everywhere, but especially in the East, arises from the fact that all attempts of the kind are made too late to be effective; the earlier cases are not segregated and the disease spreads during a period of inaction; and, for the same reason, sanitary works and measures that should

Hosted by Google

have been taken in anticipation and with a view to the prevention of disease, cannot obviously be undertaken and executed with the necessary promptitude when the epidemic is already present. But there is no other way of dealing with disease-causes, and the sooner the authorities at Bombay learn the lesson the better. It is the old story of increasing dirt, overcrowding, and neglected sanitation until the day of retribution comes in the shape of an epidemic which soon obtains a firm foothold under such circumstances.

The Municipal Commissioners of Calcutta have no time to lose if they are to turn to any practical account the warning they have received from Bombay. The *Pioneer Mail*, in adverting to the trenchant remarks of the Lieutenant-Governor of Bengal regarding the disgraceful state of certain districts in Calcutta, gives the following description of the sanitary defects of the worst parts of that city, where happily up to the present time the Medical Board are able to state that no case of true bubonic plague has yet occurred :—

"London with its population of over four millions has about 36,000 people to the square mile. In the thirteen wards of Calcutta there are only four below this figure; the remainder have from 46,000 to 144,000 per square mile, three wards being actually over the 100,000. Colootolah is most densely populated, and the houses are literally crammed with people. One case is quoted where 250 persons were living in space that should accommodate only fifty. In a hut seven feet in length, breadth, and height, five men were found, and several instances are given where similar conditions obtained. In our barracks 600 cubic feet per man is the minimum space allowed. In these *bastis* the space runs from 157 to 49 cubic feet. This would be bad enough if everything were clean and sweet in and about the huts; but as the Medical Board put the case: 'Here we find an allowance per head going as low as practically one-thirtieth of that given in barracks, and no ventilation; with filth *ad lib.* both in the room and in its surroundings, to say nothing of the filthy persons of its occupants, the sewage round in the adjacent drains and the accumulated filth in the neighbouring latrines, and to this may be added the fact that the subsoil on which the huts are built is soaked through and through with sewage matters and littered with garbage and filth of all kinds.' The narrow gullies which give access to these huts are in keeping with the general character of the *bastis*, and we may well wonder that epidemic disease is not always present."

We entirely concur with the medical authorities and the *Pioneer Mail* in thinking that the speedy application of wholesale sanitary measures is required in Calcutta; that wide roads and open spaces should be substituted for these overcrowded areas; that filthy huts and habitations should be cleared away and foul tanks and wells closed, and in that way the people compelled to have recourse to the good and wholesome water now accessible and almost carried to their doors; and that the drainage, food-supply, and other measures for improving the public health should be carried out as rigorously and promptly as practicable in the interest of all concerned. All this means money no doubt, but there is a rich community in Calcutta and the local Government must compel them to spend it.

THE LANCET RELIEF FUND.

EIGHTH ANNUAL REPORT OF THE ALMONERS.

THE LANCET Relief Fund, which has for its Almoners the President of the Royal College of Physicians of London (Dr. SAMUEL WILKS, M.D., F.R.S.), the President of the Royal College of Surgeons of England (Sir WILLIAM MAC CORMAC), the President of the General Medical Council (Sir RICHARD QUAIN, Bart., M.D., F.R.S.), Mr. THOMAS WAKLEY, F.R.C.S., and Mr. THOMAS WAKLEY, jun., L.R.C.P. Lond., with Sir HENRY PITMAN, M.D., F.R.C.P., as Honorary Auditor, came into operation on the 1st of February, 1889.

In presenting the eighth annual report the Almoners think it well again to direct attention to the object for which the Fund was established.

The Fund is sustained solely by the Proprietors of THE LANCET, who provide every January the sum of at least £300, and is administered free of cost, with the object of affording immediate pecuniary assistance to registered medical practitioners, or to the widows or orphans of members of the profession in cases of distress and emergency, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

When the Fund was inaugurated considerable misapprehension existed as to the precise objects for which it had been established; and as a result the majority of the earlier applications, being cases of *chronic* distress, and not coming, therefore, under the designation of *emergency*, could not be entertained. Attention was called to this fact in THE LANCET of Feb. 16th, 1889, in the following words :—

"We are requested by the Almoners to state that, from the character of a number of the applications received, both personally and by letter, for relief, it is evident that in many cases the object for which this Fund has been established is not quite clearly understood; and if relief had been afforded in the cases of those who suffer from chronic distress the Fund would have been completely exhausted within the first few days of its existence. They would therefore be greatly obliged if those readers of THE LANCET who may be asked to endorse applications would carefully peruse the Application Form and explain the precise object of the Fund to those applicants whose cases do not seem to come within the scope of the purpose for which the Fund has been established, which is to afford prompt aid to registered medical practitioners, or to the widows or orphans of members of the profession, who, in consequence of the supervention of some unexpected emergency, which is not likely to recur, have pressing need of immediate and temporary pecuniary relief"—and who, it may once more be pointed out, are likely to be permanently benefited thereby.

The balance in hand at the end of 1895 amounted to the sum of £77 19*s.* 10*d.* On Jan. 2nd, 1896, the Proprietors of THE LANCET placed to the credit of the Fund the sum of £300. During the course of the year repayments of loans to the amount of £25 10*s.* have been made. The sum of £350 has been granted in relief either by way of loan or of gift, leaving a balance of £53 9*s.* 10*d.* as per bank pass-book.

There have been considered altogether during the twelve months ending Dec. 31st, 1896, 37 applications for relief (the number the previous year having been 56). In 29 cases assistance was awarded, either as a loan or as a gift, according to the request of the applicant, the amounts of the grants ranging this year from £5 to £25.

In some cases of extreme urgency the application has been considered by the Almoners, the grant sanctioned, and a cheque for the amount forwarded to the applicant on the same day the application was received.

The following are extracts from letters received from some of the recipients of the Fund :—

305.—"I thank the Almoners very sincerely for their kind gift. To Mr. Wakley please present my thanks for his kindness and generosity in providing the Fund."

307.—"I am deeply grateful to the Almoners of THE LANCET Fund for their very valuable gift—how valuable only those can know who have gone through the wretched worry that I have—nearly five months without a berth, my slender stock of savings long ago exhausted, incurring debts to friends and others. Had I not been a strong man and always abstemious I must have fallen into ill-health and even destitution. I acknowledge the wisdom of the Almoners in making to me a gift instead of a loan, the repayment of which might press heavily and be a source of anxiety, whereas now should I ever become in a position to repay it I trust that I may be allowed to do so, and in that way be the means of benefiting others through the agency of your charitable work."

308.—"Kindly express our heartfelt thanks to the Almoners for enabling us to discharge the balance of the account. I can hardly express adequately the extent of our grateful feelings in thus saving our home."

321.—"Allow me to express my grateful and most sincere thanks for your kind letter. The generous and extremely benevolent gift can never be forgotten amid the painful and cheerless hours I have to pass. I shall ever feel deeply indebted to the Almoners for their kind and considerate view of my unfortunate position."

Hosted by Google

326.—"I thank the Almoners for the cheque, which comes to me much needed. I think it most kind and considerate of them to be so prompt in sending it."

330.—"I am extremely grateful to the Almoners for the generous present I received this morning. I cannot adequately express my deep thankfulness for your most timely assistance. I pray that God's blessing may be with you and that your Fund may increase and continue to extend its help to those who, like myself, are in great need."

336.—"I have much pleasure in sending you first instalment of loan. The loan that the Almoners granted me has been of the greatest good to me. I again thank them for their great kindness."

344.—"I gratefully acknowledge with sincerest thanks the receipt of cheque. Your remittance reached me within twelve hours of the time my application was received. This promptitude has relieved me of immediate embarrassment."

(Signed)

I find by the Bankers' Book that the actual balance on Jan. 1st, 1896, to the credit of the Fund was £77 19*s.* 10*d.*, to which the sum of £300 was added by the Proprietors of THE LANCET on Jan. 2nd, 1896.

The balance at the Bankers' at the present date is the sum of £53 9*s.* 10*d.* I have also checked the receipts for disbursements and find the above account strictly accurate.

December 24th, 1895. HENRY A. PITMAN, Hon. Auditor.

LOUIS PASTEUR.

THE last stage in the obsequies of Louis Pasteur was reached on Dec. 26th, 1896, when the mortal remains of the illustrious deceased were deposited in their final resting place. His death occurred on Sept. 28th, 1895, and at the funeral, which took place on Oct. 5th, the French nation honoured his memory with an impressive ceremonial and other tokens of respect displayed only when the last offices are being rendered to those who have held an exceptional position in their country's service. The President of the Republic was among the company assembled at the Cathedral of Notre Dame, the Governor of Paris was in command of the imposing military force which formed the escort, the officiating clergy included two archbishops, and the Minister of Public Instruction took a prominent part in the proceedings. The body was then deposited in the Cathedral, only, however, to remain there until a tomb or crypt suitable for its permanent reception should be constructed at the Pasteur Institute. This work having now been completed the removal of the remains was accomplished last week in presence of the family of the deceased, the staff of the Pasteur Institute, and a numerous assembly comprising men eminent in various departments of knowledge, representatives of the Government, members of learned societies, and visitors from several foreign countries. The English representatives were Sir Joseph Lister, President of the Royal Society, Sir Dyce Duckworth, Sir William Priestley, Professor Evans of Edinburgh University, and Professor Crookshank. Soon after eight o'clock in the morning mass was celebrated in the Cathedral, and on the conclusion of the service the body was conveyed in a hearse to the Pasteur Institute in the Rue Dutot, where it was received by M. Bertrand, the president, and M. Duclaux, the director. The crypt is reached by a flight of steps leading from the main entrance hall; it is ornamented with appropriate mosaic designs and has a cupola in which are emblematic figures representing Faith, Hope, Charity, and Science. Over the crypt is the inscription, "Heureux celui qui porte en soi un Dieu, un idéal de beauté, et qui lui obéit—idéal de l'art, idéal de la science, idéal de la patrie, idéal des vertus de l'Évangile." After the ceremony of consecration was completed and the coffin laid in the place prepared for it several speakers addressed the company. M. J. B. Pasteur, on behalf of the family of the deceased, formally committed the care of the tomb to the council of the Institute.

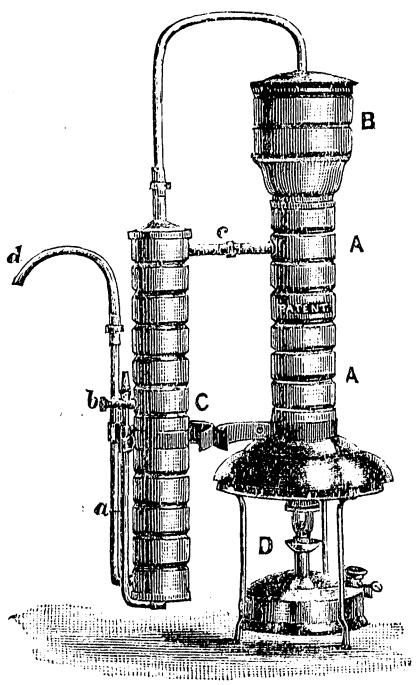
Hosted by Google

M. Rambaud, Minister of Education, enumerated some of the benefits which Pasteur's discoveries had conferred on humanity, and was followed by M. Baudin, President of the Municipality, and several others.

Sir JOSEPH LISTER said: "Je suis chargé de représenter la Société Royale de Londres, le Collège Royal des Chirurgiens d'Angleterre, et la Société Médico-Chirurgicale de Londres. Aussi j'ai fait déposer, de la part de l'Institut Britannique de la Médecine Préventive, fille de l'Institut Pasteur, une couronne ici. Il y a quatre ans, à l'occasion du jubilé de Monsieur Pasteur, j'ai eu le suprême honneur de lui présenter, au nom de la Médecine et de la Chirurgie du monde entier, l'hommage de leur reconnaissance. Aujourd'hui j'assiste à ses funérailles! Cette cérémonie est noble et imposante, digne de la mémoire de notre vénéré maître. Mais elle nous remplit d'une profonde tristesse, puisqu'elle nous rappelle que cette grande lumière de la science, si ardente et si claire, est éteinte; que ce caractère, si noble et si aimable, a disparu de notre monde."

Sir DYCE DUCKWORTH, who represented the Royal College of Physicians of London, and also, as past president, the Clinical Society of London, said: "Au nom du Collège Royal des Médecins de Londres, j'ai l'honneur de témoigner la vive sympathie avec laquelle les médecins d'Angleterre s'associent à cette touchante cérémonie. Je porte l'hommage de nos confrères à ce grand génie créateur, à ce noble caractère de Louis Pasteur. Pour nous il est un des prophètes de la science, il en est un des avant-coureurs les plus éclairés et les plus intrépides. Vénérons ensemble ce bienfaiteur de l'humanité! Vénérons ce Chrétien loyal et convaincu, dont la foi a résisté à toutes les influences matérialisantes de ses études! Que l'œuvre de Pasteur, dont les cendres reposeront désormais dans ce sol consacré par son travail, reste une des gloires impérissables de la France et du monde."

Sir W. PRIESTLEY said: "I have been appointed to represent here to-day the two Scottish Universities of Edinburgh and St. Andrews in token of respect for the memory of one who has done so much to advance the interests of science and who has conferred such signal benefits on mankind. The University of St Andrews is the most ancient in Scotland, and its authorities have in grateful recollection the kindness extended to some of its students in Paris by a committee of which M. Pasteur was chairman. The connexion of M. Pasteur with the University of Edinburgh is a more intimate one. At the celebration of the tercentenary of the University it conferred an honorary degree on M. Pasteur and received a reflected honour in enrolling so distinguished a name on its list of graduates. Those who were present on that occasion will not readily forget that magnificent ceremonial. France was represented, in addition to M. Pasteur, by Caro, Mézières, Guizot, Ferdinand de Lesseps, and my dear and lamented friend, Henri Gueneau de Mussy. I sat beside M. Pasteur, and the enthusiasm with which he was greeted knew no bounds. I had the privilege of receiving an honorary degree at the same time, and considered its value greatly enhanced by being in such company as the celebrated Pasteur and his *confrères*. Both the Universities which I represent desire to show their sincere appreciation of M. Pasteur during his lifetime and to do all honour to his memory now that he is no longer with us."



Professor CROOKSHANK spoke in the name of King's College, London.

It was observable that places of honour were assigned to the Englishmen. The public were admitted to the crypt during several hours on Sunday, an opportunity which was taken advantage of by an immense number of visitors.

THE LAWRENCE PROCESS OF SOFTENING AND STERILISING WATER.

So far as regards rendering a water absolutely safe to drink there is little doubt that heating it up to boiling point or to a slightly higher temperature and keeping it at that temperature for a time is the most trustworthy method. Filters are easily liable to accident, and defects in their construction may easily occur, while the conditions under which they can only be expected to work efficiently often fail to be secured through neglect, and that perhaps at a time when their efficient working is in special request, but boiling the water admits of no such possibilities. Satisfactory, however, as boiling the water may be from the point of view of killing pathogenic organisms, yet, as everyone knows, it deprives the water of certain of its most important qualities for drinking purposes. It becomes vapid, tasteless, and devoid of those qualities expressed by the terms "fresh," "bright," "crystal," "palatable," &c. In other words, boiling renders the water safe but not in a strict sense fit to drink. Then, again, the expense of boiling every drop of water we drink would be a somewhat formidable factor in the accounts of the household.

The boiling of water in a comparatively open vessel, as in an ordinary kettle, is obviously an extravagant proceeding; the loss by evaporation is enormous, objectionable salts that may be in solution are concentrated, and heat would be dissipated to no purpose. In the ordinary process of distilling water the heat that is expended in converting the water into steam is subsequently absorbed and lost in the water of the condenser, which is commonly run to waste. The desideratum, therefore, of a process of this kind, it seems to us, would be an apparatus in which the water could be distilled—i.e., converted into steam—and the steam condensed in the water supplying the boiler of the still, so that it would be raised to such a degree of temperature as to require but a little augmentation of heat to bring it completely to boiling point. In short, instead of losing the latent as well as the indicated temperature of the steam it should be utilised in such a way as to heat up fresh quantities of cold water preparatory to entering the boiler. In this manner the outgoing water would be cooled, softened, and of course sterilised, and the incoming water raised substantially near the boiling point, thus effecting a very important economy in the heat required. It is practically this principle which is adopted in the Lawrence apparatus, and the satisfactory application of which promises to make this method of the utmost importance and value on both economic and hygienic grounds. The accompanying illustration will make its construction and

the manner of its working clear. It represents one form of the apparatus for domestic use and consists of the following parts:—(A) The outer boiling-vessel containing an inner boiling cylinder (B) with enlarged top. (C) A heat-interchanger by means of which the heat is transmitted from the boiled water to the crude inflowing water. (D) The lamp or heater which serves to supply the few degrees of heat not interchanged by the apparatus (C).

Hosted by Google

In action the water flows in cold through the small supply-pipe *(a)*, the rate of flow being regulated by the cock *(b)*, and enters the heat-interchanger at the bottom. Rising upwards, internally, it arrives at the top of the interchanger (C) at about 180° F., and passing into the top chamber of the inner boiling-vessel (B) thence passes downwards through all the chambers or locators, about twenty in number, where it is met constantly by the ascending steam or vapour of ebullition. These chambers, in series, really constitute a sort of "scrubbing tower" in which the ascending steam is brought into very intimate contact with the water. In addition, the tower is packed with a column of discs in a vertical position, which in shape are not unlike the screw propeller of a ship. Their function is to bring about complete contact of the steam with the water, while the slight resistance which they offer to the upward passage of the steam is calculated to raise the temperature somewhat above boiling point.

The water having become successively deposited in these locators arrives at the lowest chamber, whence it takes an upward course between the inner and outer cylinders, flows back to the heat-interchanger, through the pipe (C) and, becoming cooled by the inflowing water, makes its escape at *(d)* in a cooled state. A certain amount of aeration is effected in this pipe by means of a small hole at the top of the bend, bubbles of air being sucked in by the action of the descending stream. The temperature at which it emerges depends upon the rate of flow; about 20° of difference is practically maintained between the inflowing and outflowing water where the quantities of each are equal. Thus, if the crude water enter at 50° F. the softened outflowing water will be 70° F. or thereabouts. When, however, a portion of the water is required as hot water and the remainder as cold these temperatures are modified. A domestic apparatus of twelve gallons per hour power, with additional interchanging power when worked at eighteen gallons rate of flow, delivering hot water at seven gallons and cooled water at eleven gallons, gives, as found by experiment, the hot water a temperature of 160° and the cold 8° only above that of the inflowing water, which, supposing it was originally at 50°, would give 58° for the softened water.

The prevention of incrustation is provided for by the inner boiling cylinder being removeable as well as the boiling and depositing chambers contained in it. The incrustation being soft and friable is quickly shaken off.

The softening effect of the apparatus upon hard water can be modified to suit individual requirements. Water such as that in the hard chalk districts and the London tap water may be reduced, as our experiment showed, to 6° or 7°. This applies to the London tap water with an initial hardness of 16° or of other water showing a hardness of 20°.

Applied to industrial purposes the following is the statement of the inventor of this apparatus in regard to cost. The few degrees of heat necessary to transform the water from hard to soft can usually be found in the shape of waste heat, and where both warm and cold water are required the cost of treatment is reduced to *nil*. Where, however, no waste heat can be provided and the heat has to be obtained from the steam boiler the cost is as nothing compared with the saving effected in fuel by the prevention of incrustation and wear and tear and cleaning out of boilers. The accepted estimate of cost for fuel for evaporating 1000 gallons of water is 7*s*. 6*d*. and the cost of bringing the water from 50° F. to boiling point is 1*s*. Given this rate the cost of softening by the Lawrence process would be about one-eighth that of boiling in the ordinary way—that is, 1½*d*. per 1000 gallons in lieu of 1*s*. per 1000 gallons. And, moreover, practically the whole of the heat is returned to the boiler. Since, however, the accepted saving in coal where a boiler is always kept in a perfect condition of efficiency is at least 15 per cent. the economy of the Lawrence process, apart from the saving of wear and tear, is still more manifest.

For domestic drinking purposes, in particular, this apparatus, it is said, has the advantages of being cheap, light, very portable, and not liable to get out of order. To give some idea of its lightness and portability an apparatus capable of heating and cooling 150 gallons per hour, specially designed for military purposes, may be carried by one man. Further, a very important application of the method is to milk, which can be sterilised in large quantities in a modified form of this apparatus and delivered partially cooled.

Our own experiments with the Lawrence apparatus have been directed chiefly to ascertaining its softening power upon hard waters and as to how far it could be trusted to produce a pure and sterile effluent. We have already recorded an experiment establishing its capacity for greatly reducing the hardness of chalky water. Thus in the case of the New River (London) supply the hardness was reduced from 16° to 6°, a reduction of 10 degrees, and in some cases somewhat lower.

In regard to bacteriological experiments the action of the apparatus was first tested on the ordinary tap water which was supplied by the New River Company to ascertain whether the ordinary water organisms were destroyed and the fluid thus rendered sterile. An emulsion of the common pus organism, staphylococcus pyogenes aureus, was then mixed with this tap water and subjected to the sterilising process. As this organism exhibits a resistance to heat and antiseptic substances somewhat greater than that manifested by the bacillus typhosus and Koch's cholera bacillus, the two most important disease organisms usually supposed to be transmitted through drinking-water, we may conclude that if the pus organism is destroyed the disease organisms referred to would share a similar fate. As a final and severe test an emulsion from a potato bacillus culture containing very resistant spores was passed through the apparatus. In the experiments with New River water the following results were obtained:—

Number of colonies present per c.c. in original water, from 60 to 80; number of colonies present per c.c. in water after process, none. It will be seen from this that the water was rendered absolutely sterile as it issued from the apparatus. In the experiment with staphylococcus aureus the following results were obtained:—

Staphylococcus pyogenes aureus.—Staphylococcus aureus present in 1 c.c. original fluid, many colonies; staphylococcus aureus present in 1 c.c. of fluid after process, none. We may conclude from this experiment that the disease germs transmitted through drinking water, which are non-sporebearing, would by this process be rendered innocuous. In the experiments with potato bacillus the following results were obtained:—

Potato bacillus.—Potato bacillus present in 1 c.c. original fluid, many colonies. Potato bacillus present in 1 c.c. of fluid after process, none. This experiment would seem to indicate that these very resistant spores had been completely destroyed; but this conclusion is rendered doubtful by a further test to which this fluid was subjected—viz., a larger quantity of the fluid was taken and added to a flask of broth and incubated at 30° C. for three days. When examined it was found that a film of the potato bacillus had grown over its surface. In this experiment where we are dealing with a larger quantity of the fluid the possibility of the entrance of this organism (which is a very common chance contamination) is not absolutely excluded, but it seems more probable that all the spores are not destroyed during this process. It is, however, probable that by making the column of the boiling chamber higher an increased columnal pressure of water acting upon the rising steam would be obviously obtained, and accordingly the temperature would attain several degrees above 212° F., in which case the sterilising efficiency of the apparatus would be absolute. The experiments made with a small domestic apparatus indicate as a whole, however, that this process would render a water harmless so far as regards the transmission of specific infective disease by means of water.

The apparatus offers not the slightest difficulty in working, it is perfectly continuous, and the source of heat may be gas, oil, or an ordinary coal fire. The fact of it reducing to a very considerable extent the hardness of hard waters is alone important both from an economic and hygienic point of view. We understand that the plant is already in use producing soft water on a large scale for industrial purposes where the danger of incrustation in steam boilers must be most carefully avoided. We are more concerned with its merits as a purifier of water for drinking purposes, and our experiments have established that for this purpose its action is excellent. The water it yields is perfectly clear and bright, palatable yet soft to the taste, while, above all, it gives absolute security against the possibility of water for domestic drinking purposes becoming a source of infection or disease

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Manchester Sanitary District.—Dr. Niven's report for the year 1895 is, as are all his reports, full of interest, and it bears indication of an enormous amount of work. The statistics of Manchester are dealt with in a manner which is highly instructive, and the figures relative to age and district distribution will be of great local value. With reference to the vital statistics of Manchester as a whole it is encouraging from a commercial standpoint to note that the marriage and birth rates both show a considerable increase on the rates for 1894; but, on the other hand, it is to be remarked that the death-rate allows, as Dr. Niven terms it, of no such cheerful reflection, since this rate was exceeded only by those of Liverpool and Salford. There was, indeed, a net loss, as compared with the figures of 1894, of over 1000 lives, the increased mortality being chiefly recorded under diarrhœa, certain infectious diseases not directly controlled by the sanitary authority, constitutional, circulatory, and respiratory diseases. The figures for 1895, however, showed marked diminution from diseases of the nervous system, and Dr. Niven thinks that the decrease under the heading "convulsions" may be due to the improved methods of infant feeding. Respiratory diseases Dr. Niven regards as partly due to the atmosphere of certain parts of Manchester and to the habits of the people, and also to the effluvium arising from the insanitary condition of the ground; in fact; the filthy state of the soil, which is caused by defective pails and privies, is matter for special condemnation at the hands of Dr. Niven on several accounts. The infantile mortality of Manchester for 1895 rose with that of the whole country and amounted to no less than 203 per 1000, diarrhœa, measles, and wasting diseases being chiefly responsible for the deaths. The section of Dr. Niven's report which deals with scarlet fever is of considerable originality. Space is also devoted to the interesting subject of "return" cases of scarlet fever, a matter to which Dr. Niven has paid much attention. He is inclined to think that the storing up of infection in the nasal cavities, and possibly also the lungs, of discharged patients, is the most frequent source of mischief, and he considers that the inhalation of a highly-infected atmosphere, such as is met with in hospital wards, is more likely to lead to the storing up of infection than would be the case in a child isolated at home. The figures, too, which Dr. Niven adduces tend to show that the "return" cases in Manchester are due to something connected with the discharged patient, and he is not inclined to think that the unpacking of some imperfectly disinfected article on the return of the patient from hospital is a very potent agent in the causation of "return" cases—at any rate, under the conditions of disinfection which are now practised in Manchester. The conclusion at which Dr. Niven arrives has led him to advocate that all children shall pass through the relatively little infected atmosphere of a convalescent ward before discharge, and that the mouth and nostrils should be carefully sprayed with some non-irritant antiseptic. The methods adopted for the bacteriological examination of cases of diphtheria in Manchester are such as must facilitate enormously the work of medical practitioners. It is possible, it seems, to telephone to the Health Office for a tube, to have it conveyed to the medical man's residence or to the patient's home by special messenger, and to despatch the charged tube by means of the same messenger to the bacteriological laboratory. It is furthermore arranged that in the event of the bacteriological examination yielding negative results the notification fee is nevertheless paid to the medical practitioner. All these facilities have been so appreciated by the profession that a bacteriological examination is made in almost every living case and occasionally in instances where death has taken place. It is interesting to note that out of a series of 106 cases examined, in thirty-five only were positive results obtained. One of the effects of these bacteriological examinations will be, Dr. Niven points out, to modify very materially what was previously the apparent distribution of diphtheria in Manchester, as it has been shown that the majority of cases which were not diphtheria were scarlet fever. In connexion with the subject of diphtheria Dr. R. W. Marsden contributes a report upon the use of antitoxin, and he speaks most highly as to its value, more especially in the direction of aiding the disappearance of membrane and in reducing the effects of toxæmia. Dr. Marsden has never seen serious results follow the injection of the serum. Dr. Niven devotes considerable space to the subject of enteric fever, and although there is much difficulty in detecting the origin of many cases he finds that the condition of the privies and of the ground connected with them has in Manchester a decided effect in the production of typhoid fever; and he further shows that the middens assert their influence chiefly in autumn — i.e., when the activity of the soil in relation to germ multiplication is probably at its highest. We notice, by the way, that the privies in Manchester are disinfected when necessary by a solution of chloride of lime, three ounces to the gallon. Under Dr. Niven's advice measles is not yet notifiable in Manchester, but a system is in force by which the school attendance officers diffuse information and advice in respect of this disease and of whooping-cough. The subject of the notification of tuberculosis is again discussed by Dr. Niven, and he reports his recommendation of last year that Manchester should lead the way in this matter.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 4780 births and 3545 deaths were registered during the week ending Dec. 26th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 19·4 to 18·2 per 1000, further fell last week to 17·0. In London the rate was 15·1 per 1000, while it averaged 18·4 in the thirty-two provincial towns. The lowest rates in these towns were 11·0 in Croydon, 12·3 in Derby, 12·5 in Brighton, and 13·4 in Birkenhead; the highest rates were 21·5 in Preston, 21·7 in Blackburn, 22·0 in Hull, and 31·8 in Plymouth. The 3545 deaths included 279 which were referred to the principal zymotic diseases, against 356 and 357 in the two preceding weeks; of these, 68 resulted from diphtheria, 64 from whooping-cough, 60 from measles, 32 from "fever" (principally enteric), 29 from scarlet fever, and 26 from diarrhœa. No death from any of these diseases was recorded last week in Croydon or in Swansea; in the other towns they caused the lowest death-rates in Brighton, Bolton, Burnley, and Oldham; and the highest rates in Salford, Nottingham Blackburn, and Plymouth. The greatest mortality from measles occurred in Nottingham, Gateshead, Bradford, and Plymouth; and from whooping-cough in Birkenhead, Salford, Huddersfield, and Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 68 deaths from diphtheria included 38 in London, 6 in West Ham, and 3 in Liverpool. No fatal case of small-pox was registered during the week under notice either in London or in any other of the thirty-three large towns. There were no small-pox cases under treatment either in the Metropolitan Asylum Hospitals or in the Highgate Small-pox Hospital during the week ending Saturday last, Dec. 26th. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3763, against numbers declining from 4164 to 3868 at the end of the nine preceding weeks; 219 new cases were admitted during the week, against 350, 353, and 291 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the six preceding weeks from 492 to 302, further fell to 284 last week, and were 318 below the corrected average. The causes of 60, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Oldham, Newcastle-upon-Tyne, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns,

Hosted by Google

which had increased in the three preceding weeks from 20·4 to 21·0 per 1000, further rose to 22·1 during the week ending Dec. 26th, and exceeded by 5·1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 12·0 in Perth and 14·0 in Leith to 23·5 in Dundee and 26·0 in Glasgow. The 644 deaths in these towns included 106 which were referred to the principal zymotic diseases, against 68 and 98 in the two preceding weeks; of these, 48 resulted from measles, 26 from whooping-cough, 16 from diarrhœa, 8 from scarlet fever, 4 from diphtheria, and 4 from "fever." These 106 deaths were equal to an annual rate of 3·7 per 1000, which was 2·4 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 40, 37, and 54 in the three preceding weeks, declined to 48 last week, of which 41 occurred in Glasgow, 4 in Paisley, and 3 in Aberdeen. The deaths from whooping-cough, which had been 9 and 7 in the two preceding weeks, rose again to 26 last week, of which 20 were recorded in Glasgow and 3 in Edinburgh. The 8 fatal cases of scarlet fever exceeded the number registered in any recent week, and included 5 in Glasgow and 2 in Dundee. The deaths from diphtheria, which had been 9, 2, and 7 in the three preceding weeks, declined to 4 last week, of which 2 occurred in Greenock. The 4 fatal cases of "fever" included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 170 and 121 in the two preceding weeks, rose again to 152 last week, and were 10 above the number in the corresponding period of last year. The causes of 31, or nearly 5 per cent., of the deaths in these eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·8 and 27·3 per 1000 in the two preceding weeks, declined again to 26·5 during the week ending Dec. 26th. During the past thirteen weeks of the current quarter the death-rate in the city has averaged 26·3 per 1000, the rate during the same period being 17·9 in London and 17·5 in Edinburgh. The 178 deaths registered in Dublin during the week under notice showed a decline of 5 from the number in the preceding week, and included 21 which were referred to the principal zymotic diseases, against 21 in each of the two preceding weeks; of these, 15 resulted from whooping-cough, 3 from scarlet fever, 2 from measles, 1 from "fever," and not one either from small-pox, diphtheria, or diarrhœa. These 21 deaths were equal to an annual rate of 3·1 per 1000, the zymotic death-rate during the same period being 1·0 in London and 0·8 in Edinburgh. The fatal cases of whooping-cough, which had been 4 and 12 in the two preceding weeks, further rose to 15 last week, and exceeded the number recorded in any week since February, 1886. The deaths referred to scarlet fever, which had been 10 and 5 in the two preceding weeks, further declined to 3 last week. The mortality from "fever" was also below that recorded in any recent week. The 178 deaths in Dublin last week included 30 of infants under one year of age, and 32 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers returned in the preceding week. Thirteen inquest cases and 8 deaths from violence were registered; and 58, or nearly a third, of the deaths occurred in public institutions. The causes of 10, or nearly 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-CAPTAIN THOMAS has been posted to Hounslow for duty. Surgeon-Captain Jackson has embarked for foreign service. Surgeon-Captain M. P. Holt has left for India. Surgeon-Captain J. W. Jennings has been selected for employment with the Egyptian Army. Surgeon-Captain H. A. Haines has been posted for duty to Cork. Surgeon-Major White has taken over charge of officers, women, and children, and female hospital at the Curragh Camp, from Surgeon-Major G. T. Trewman. Surgeon-Captain V. H. W. Davoren has been posted for duty to the Royal Infirmary, Dublin.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain R. M. Moir, Resident Surgeon, Presidency General Hospital, is appointed to act as First Resident Surgeon of that institution until further orders. Surgeon-Captain F. O'Kinealy is appointed to do general duty at the Presidency and to act as Second Resident Surgeon, Presidency General Hospital, until further orders. Surgeon-Major G. Jameson, Civil Surgeon of Tippera, is appointed, on return from furlough, to act as Civil Surgeon of Nadia, and Surgeon-Major J. F. Tuohy, Civil Surgeon, to the Saharanpur District until further orders. Surgeon-Major G. M. J. Giles, Civil Surgeon, is transferred from Saharanpur to Sitapur. Surgeon-Major E. S. Brander, Civil Surgeon, is transferred from Sitapur to Jhansi. Surgeon-Major G. Shewan, Officiating Civil Surgeon, is transferred from Jhansi to Bijnor. Surgeon-Captain Daly, on arrival from England, has been posted to the Bombay District.

NAVAL MEDICAL SERVICE.

Deputy Inspector-General Robert Hay, M.D., is appointed to Bermuda Hospital, vice Deputy Inspector-General Thomas Browne, time expired, who has been appointed to Stonehouse.

The following appointments are announced: — Fleet-Surgeons: Valentine Duke to the *Vivid;* Thomas C. Hickey to the *Thunderer;* Edward W. Luther to the *Repulse;* Alfred T. Corrie to the *Durham;* and Archibald M'Kinlay to the *Resolution.* Staff Surgeons: Donald Hoskyn to the *Centurion;* and Harold R. Osborne to the *Hermione.* Surgeons: C. H. Upham to the *Torch;* Bernard Ley to the *Lapwing;* Murray P. Jones to the *Resolution;* John A. L. Campbell to the *Stork;* and Richard H. Way to the *Sharpshooter.*

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant Alexander Macdonald, M.B., the Queen's Rifle Volunteer Brigade, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: The Tynemouth (Western Division, Royal Artillery): John Cromie, gent., to be Surgeon-Lieutenant. 1st Cornwall (Duke of Cornwall's Western Division, Royal Artillery): Surgeon-Lieutenant Leonard Frank Houghton is appointed Second Lieutenant. *Rifle:* 5th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant T. Wood, M.B., to be Surgeon-Captain. 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Major A. D. MacDonald, M.D., to be Surgeon-Lieutenant-Colonel. 5th Volunteer Battalion the Cameronians (Scottish Rifles): Surgeon-Major H. Arthur, M.D., resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement.

SANITARY STATE OF CALCUTTA.

The very trenchant remarks of Sir Alexander Mackenzie, the Lieutenant Governor of Bengal, in his late speech as to the state of some of the worst districts of Calcutta have not, we hope, been without their effect on the municipal authorities of that city. The report of the Calcutta Medical Board has roused the attention of the Local Government to the subject, and it is certain that some action will have to be taken to improve the existing state of things. The Medical Board has begun to take evidence regarding the sanitary condition of the city. They are empowered to call any witnesses they may desire.

MILITARY INVALIDING FROM INDIA.

The *Times of India* of Dec. 12th states that, in spite of the agitation of a few months ago, the arrangements for invaliding seem to be more faulty than ever. Invalids who passed a medical board as far back as September last were many of them still at Deolale awaiting passage home. Our Indian contemporary asks, how long it will take the authorities to learn to bow to the inevitable, and to provide special accommodation for the sick? There can be no doubt, we think, that steamers specially fitted and provided for the purpose should be set apart for the sick returning from India.

DEATHS IN THE SERVICES.

Surgeon-Lieutenant-Colonel Francis Cobham Nicholson, A.M.S. (retired), on Dec. 24th, aged fifty-one years. He

entered the Army in 1869, and reached the rank of Brigade-Surgeon-Lieutenant-Colonel in 1894. He served with the Looshai expedition, and received the medal with clasp.

DR. YERSIN'S ANTITOXIC SERUM.

It is stated that a small quantity of Dr. Yersin's antitoxic serum, to the use of which in the treatment of plague we have more than once referred, is on its way to Bombay and will be employed in the treatment of cases in that city.

GOOD SERVICE PENSIONS.

The Queen has approved of the grants of £100 a year as Good Service Pensions to Surgeon-Major-General J. Jameson, M.D., Director-General of the Army Medical Department, and to Surgeon-Major-General C. H. Giraud, retired pay.

Correspondence.

"Audi alteram partem."

"THE ELECTION OF DIRECT REPRESENTATIVES TO THE GENERAL MEDICAL COUNCIL."

To the Editors of THE LANCET.

SIRS,—I am unwilling at this season of peace and goodwill to write anything which could give umbrage to any of those from whom it is my fate to differ, or which could fan into flame the expiring embers of a finished controversy. I therefore propose to leave unnoticed such passages in the letters contained in THE LANCET of Dec. 26th as may either be, or appear to be, provocative, and to content myself with offering a few words of simple disclaimer or explanation. In the first place, I do not quite know what Dr. Drage means by the "success of" my "friends." The word "friends" is not used, I imagine, to express personal friends, but only persons with whom one has been working for the attainment of some common end. With reference to the election, there are no persons who stand to me in this relation. Except in the case of Dr. Glover, I have yet to become acquainted with the successful candidates, and I took no part in promoting their election. I neither advocated nor depreciated the claims of any candidate and I did not vote. I have never voted at a Council election and I do not intend ever to vote at one. I was indifferent as to the result. There was no candidate whose published opinions were sufficiently like my own to induce me to accept him as my representative; and I felt entire confidence that the gentlemen elected, even if they held erroneous opinions about the duties of the Council at the time of their election, would soon have such errors corrected by experience and responsibility.

I expressed my feeling that the Medical Defence Union had been unwise in meddling at all with the election, and I pointed out the light in which, as it seemed to me, its action might be viewed by impartial persons. But I did not even suggest the view of the case which Dr. Drage repudiates, that the candidates favoured by the union were partners to any bargain restrictive of their entire freedom of action. They were presumably selected by the union on account of views which they were supposed to hold; but I did not even go so far as to say that, from the union point of view, the selection had been judicious.

Dr. Drage's concluding paragraph contains an expression of thankfulness to practitioners who voted for him, "notwithstanding the virulent attacks of *such men* as Mr. Carter and his friends." Here, again, I am perplexed. The construction of the sentence does not make it quite clear whether the "attacks" referred to were made actually by me and by my friends or by other persons our congeners; but it seems plain, from the use of the word "notwithstanding," that they were made before the election. In this connexion, as already explained, I have no "friends." I have never made any attack on Dr. Drage, either virulent or otherwise, in my life, nor have I seen or heard of any attack or attacks upon him by others; nor can I conjecture why he should have been attacked by anybody. Dr. Drage continues that my "enmity" and that of my "friends" is a "compliment." On this point I hope there may be differences of opinion; but my "enmity" is at least a compliment which has never been paid to Dr. Drage. My knowledge of him is insufficient to afford a basis either for enmity or friendship, and I have never thought of him at all except as a professional brother of some distinction, with whose views, as far as I knew them, I did not always agree. May I add, in reply to other correspondents, that the reason why I think direct representation a farce is because the functions of the Council, which depend upon Acts of Parliament and judicial interpretations, and not, as supposed by Mr. Dickinson, upon the "views" of the members, do not include any in the discharge of which direct representatives have any advantage over other people? I think that the leaders of the movement for direct representation confounded a means with an end. They obtained their representatives without reflecting how little there would be for them to do. They should first have sought to increase the powers of the Council and only afterwards to modify the composition of the body by which the powers were to be exercised. Either they did not perceive this or they found that any attempt to obtain increased powers would be fruitless. All that they gained was an illusory concession, which left the Council with its original duties of protecting the public against inadequate medical education and against unworthy members of the profession, but which gave it no means of doing anything more. As for the reasons for the retirement of Sir Walter Foster and Mr. Wheelhouse I should like to remind Mr. Colin Campbell that a general understanding is often only a misunderstanding, and to quote to him your own statement, that the reasons which actuated these gentlemen "have never been fully understood." I believe I am acquainted with some of them, but only from private conversations which it would be indecorous to repeat, even if I could be sure of repeating them correctly. Finally, it is not quite accurate to say that I "think little" of the votes cast in favour of the successful candidates. The truth is rather that I look at both sides of the balance and that I think also of the votes which were cast against them. It will be time enough to compare the votes given for direct representatives with those given for corporation representatives when any members of the latter class are found to rest their claims for consideration upon the numerical magnitude, instead of upon the character and the fitness, of their respective constituencies.

I am, Sirs, your most obedient servant,

Harley-street, W., Dec. 29th, 1896. R. BRUDENELL CARTER.

To the Editors of THE LANCET.

SIRS,—Lest silence on my part, under the circumstances, should be misconstrued, will you also kindly allow me through the medium of your columns to cordially thank the 564 members of the profession in Scotland for the honour which they did me in giving me the very substantial and perfectly spontaneous support which they did? Late of appearing in the contest as I was, and with no organisation, not even the services of a law agent, the election in Scotland clearly demonstrated two things—first, that there is a large feeling of dissatisfaction in Scotland with the present state of medical economy; and secondly, contrariwise, that there exists a remarkable indifference to the remedying of it. Out of a constituency of close upon 4000, not 50 per cent. took the trouble to return their voting papers, so that the present representative may be held as personifying the views of about one-third of the constituency. If absolute demoralisation and disintegration of the profession, which imminently threaten, are to be averted the first step to be taken is in the direction of a new Medical Act, and with a united profession throughout the kingdom this could soon be an accomplished fact.—I am, Sirs, yours faithfully,

Glasgow, Dec. 29th, 1896. D. CAMPBELL BLACK.

To the Editors of THE LANCET.

SIRS,—Mr. Brudenell Carter's analysis of the poll[1] is both useful and instructive, but when he uses his figures for the purpose of condemning the principle of direct representation his deductions are somewhat startling. That he, of all men, should argue that none of the gentlemen recently elected represents an appreciable number of the profession is very curious. I believe Mr. Carter holds his seat through the patronage of a few wardens of the Apothecaries' Society, the election to this position, as in the case of the "Worshipful Masters" in the other like City companies, such as the Tallow-chandlers, Cutlers, Plumbers, &c., being conducted after the

[1] THE LANCET, Dec. 19th, 1896, p. 1789.

Hosted by Google

doctrine of "Apostolic Succession," with the difference that on this principle the Church ensures the undoubted merit and high position of the members upon whom honour is conferred. In the case of the companies, however, there is no such guarantee; the most popular member socially and the man who knows best how to dine well is generally pushed to the front. That the Apothecaries' Company happens to be represented on the General Medical Council by so able an advocate of its peculiar claims as Mr. Brudenell Carter is quite an accident, and the power behind him is practically represented by the votes of probably five electors, more or less, and of the value of their judgment and capacity for selection we know but little. Dr. Rentoul will be able to enlighten the Council and the profession upon this matter, for Mr. Carter will find in his new colleague an expert in knowledge of all *the little ways* of the "close corporations." Mr. Carter assures us that direct representation is now removed from the range of practical politics. I would remind this gentleman that it is but a short time since this was said of the Parliamentary franchise, and he may be perfectly satisfied that universal direct representation of the profession upon the General Medical Council will be adopted in the near future, for the Statute of Limitation has no place in such matters.—I am, Sirs, yours faithfully,

Old Trafford, Dec. 22nd, 1896. JAMES BRASSEY BRIERLEY.

THE EIGHTH INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY: PUBLICATION OF TRANSACTIONS.

To the Editors of THE LANCET.

SIRS,—I beg to inform you that the Transactions of the Eighth International Congress of Hygiene and Demography held at Budapest in September, 1894, are now ready for publication, and the remaining seven volumes will be sent out early in January, 1897. As many members might have since changed their residence, I would feel greatly obliged if you would kindly publish this note in your valuable periodical in order that members might be able to send in their addresses in time to the Editor (Dr. Sgmd. de Gerlóczy, St. Rochus Hospital, Budapest). An extra copy of the Transactions will be also sent to you for your own use.

I remain, Sirs, yours obediently,

Budapest, December, 1896. Dr. GERLÓCZY (The Editor).

THE REPORT OF THE ROYAL COMMISSION ON VACCINATION.

To the Editors of THE LANCET.

SIRS,—A weak result of a weak-kneed Commission, or as you better, certainly more Parliamentarily, put it, "Once more we have to point out that the omission to recommend re-vaccination as an administrative duty constitutes the one great flaw in the very valuable deliverance of the Commissioners." It would be well, if vaccination is to be saved to us in its whole utility, for some sound-minded member of the profession, with good time on his hands and living near the British Museum, to work through, from the time of Jenner's stupendous discovery, a dozen newspapers—say six London and six provincial ones—and to give the public in cheap pamphlet form quotations from each newspaper for each year, especially those with reference to the delight of the public in the gradual diminution of the effects of small-pox—viz., mortality, loss of noses and eyes, and general pitting of the faces—also noting the reports from foreign countries which show equal delight in the use of vaccination and, as the years went on, the value of re-vaccination. Injury from vaccination—such as erysipelas and syphilis—I take it, would be avoided if no vaccination was made except from calf vaccine supplied by Government or their recognised agents, or possibly, by public vaccinators—in this latter case with lymph only *once* removed from calf. I say, "possibly," because I have reason to believe from my small experience that vaccination with calf lymph sometimes fails and that vaccination only succeeds when humanised calf lymph is used.

I would say let Parliament make vaccination and re-vaccination compulsory, and each for the first time to be made with calf vaccine; on failing to repeat with calf vaccine; but on second failures that once humanised calf lymph should be used. I am, Sirs, yours faithfully,

Canterbury, Dec. 25th, 1896. PUGIN THORNTON.

"THE NEW SYDENHAM SOCIETY'S MEDICAL LEXICON."

To the Editors of THE LANCET.

SIRS,—Mr. Kesteven's letter on the slow rate of publication of the New Sydenham Society's Medical Lexicon deserves some attention from the council of the society. I attended the last annual meeting of the society and urged that an attempt should be made to conclude the Lexicon before the close of the century. There was not a large meeting of members, only about half a dozen being present; but this, I am informed, is the usual number who attend on such occasions. The society has a president, 16 vice-presidents, 32 members of council, 1 treasurer, 3 auditors, and 1 honorary secretary, but none of these officials were present and no one could explain the slow rate of progress in the publication of the Lexicon. The chairman, however, promised to forward a strong representation of the wishes of the meeting that some effort should be made to bring the publication to a conclusion.

I am, Sirs, yours faithfully,

Carlisle, Dec. 28th, 1896. HENRY BARNES, M.D. Edin.

"ALLEGED ARSENICAL POISONING."

To the Editors of THE LANCET.

SIRS,—Dr. Murrell has written his letter[1] under a misapprehension. I stated that the fabric to which he refers contained approximately $\frac{1}{10000}$th of a grain of arsenic per square yard. In this I was supported by Mr. W. Thomson, who found the same proportion. This is only one part in 1,300,000 of the fabric. Hence Dr. Murrell's criticisms on what he supposes I said fall to the ground. Every point to which he refers was fully before the court—the delicacy of the tests for arsenic and for determining its amount when admixed with organic matter, the proper doses when taken by the mouth, and the influence of inhalation upon the dose.

I am, Sirs, yours faithfully,

Guy's Hospital, Dec. 29th, 1896. THOMAS STEVENSON.

"THE TRAINING OF NURSES IN RELATION TO REGISTRATION."

To the Editors of THE LANCET.

SIRS,—If you had waited to hear the other side of the story your correspondent has told you you would have found that the feeling of discontent to which you refer as arising among the members of the Royal British Nurses Association is limited to a small minority. The facts are these. A proposal was laid before the council of the association in July last to admit *properly trained and qualified* mental nurses into the association. This matter was referred to a committee of the council who reported strongly in favour of the proposal, and the report was unanimously adopted. Now before the details have even been discussed by the executive committee a letter has been sent out signed by Sophia Wingfield, protesting against the admission of "*untrained asylum attendants* as members of the association," and stating that once the "asylum attendants are admitted as registered members of the corporation of trained nurses the public will have no means of protecting themselves against untrained persons." This is not the case. The proposal is that none but mental nurses of not less than three years' training in a hospital or asylum for the insane with not less than forty beds shall be admitted to registration, and it will be necessary for each nurse to possess the certificate of the Medico-Psychological Association for proficiency in nursing. This certificate can only be procured after a rigid curriculum of instruction and practical tuition and training in the nursing of the sick and insane now carried on in every hospital and asylum in the kingdom under the direction and practical instruction by the medical staff and attendance upon courses of lectures and demonstrations followed by stringent

[1] THE LANCET, Dec 26th, 1896.

Hosted by Google

examinations inferior to no examinations for hospital trained nurses—nay, vastly superior to many.[1] These are the nurses it is proposed to admit to the register as a distinct class with a separate department in the register, a separate and distinct badge, and to be enrolled as M.N.R.B.N.A.—that is, mental nurses of the association—to distinguish them from the purely hospital trained nurses. It is for the protection of the public that this proposal is brought forward. No nurses are more urgently required than those specially trained and educated to nurse mental cases. The ordinary hospital trained nurse will not, and could not if she would, undertake them; and it is by placing all those who are worthy of the confidence of the public upon the published register of the association that the public will be enabled to ascertain whether they are properly trained and qualified for their work.

The royal charter of the corporation especially provides for them "to affiliate to themselves or amalgamate with themselves or enter into any arrangements for wholly or partially working in conjunction with any person or any body of persons, corporate or unincorporate, formed for all or any of the purposes for which the corporation themselves are formed or for any purposes analagous or corresponding thereto. As a matter of fairness to those highly qualified mental nurses and of justice to the public it is proposed to place them on the published register of the association.

I am, Sirs, your obedient servant,

T. OUTTERSON WOOD, M.D. Durh.,
Member of the Executive Committee and of the Registration Board of the Royal British Nurses Association.

Margaret-street, W., Dec. 26th, 1896.

*** Our remarks on Dr. Wood's explanation, which appears to us entirely satisfactory, will be found in an annotation dealing with this subject.—ED. L.

"GUAIACOL AND CREOSOTE IN PULMONARY PHTHISIS."

To the Editors of THE LANCET.

SIRS,—Some of your readers may be glad to know that a considerable reduction has been effected in the prices of carbonates of creosote and of guaiacol, so that it is now possible to prescribe them in cases where formerly the cost was prohibitive. A letter appears in THE LANCET of Dec. 19th, 1896, from Dr. Jones-Humphreys which calls for a few remarks. I am pleased to see that he is able to confirm my statements as to the value of this group of remedies; but I think he fails to prove a "specific action" of guaiacol on the kidneys in albuminuria. No doubt it has an action on some kinds of albuminuria, as his own case shows. But this action is probably indirect and depends on the destruction of some other irritant; and it would be unsafe without more evidence to conclude that the drug will be equally useful in albuminuria, say, after scarlet fever. The formula which he gives will answer well when small doses of guaiacol are prescribed; but such a mixture would have to be taken by the pint in some cases, which would be inconvenient, to say the least. There are few remedies with a wider range of dosage, and the best dose in each case is very much a matter of experience.—I am, Sirs, yours truly,

F. R. WALTERS, M.D., M.R.C.P. Lond.

Welbeck-street, W., Dec. 28th, 1896.

HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—At the request of the Hospital Reform Association Dr. W. Knowsley Sibley and Dr. Ernest Snape have kindly undertaken to make a report on the special hospitals of the metropolis. The association will feel grateful if the officers of these institutions will afford them facilities for making their report as complete as possible.

I am, Sirs, yours faithfully,

Cardiff, Dec. 28th, 1896. T. GARRETT HORDER, Hon. Sec.

[1] There are now about 2000 of these certificated nurses on the register of the Medico-Psychological Association, but the register is not published.

"MIRROR SPEECH."

To the Editors of THE LANCET.

SIRS,—Dr. Marcel Baudouin, whose signature is appended to a short article[1] on Dr. Doyen's unique case,[2] informs his readers that he himself is a born *gaucher*, and confirms an observation made some time ago in THE LANCET,[3] that to many markedly left-handed persons mirror writing comes naturally. I happen to be likewise a born "kithogue," as they say in Ireland, and having now for the first time essayed the mirrorwise feat beg to add my humble testimony to that of the distinguished Vendean writer. The term left-handed is generally regarded as depreciatory; in fact, according to the dictionary, its synonyms are in English awkward, clumsy, stupid, insincere, malicious; while in French *gaucherie* is the usual word for uncouthness. From the point of view of a kithogue this philological syllepsis is a genuine grievance—an injustice foisted on the few through the overweening complacency of the majority. There is nothing essentially awkward or uncouth in making use of the left hand for actions ordinarily performed with the right. The uncouthness really exists in the eyes of the right-handed multitude, who vainly imagine that their way of doing a thing must necessarily be the only correct way. Of course, a left-handed person may be awkward, &c., but so are many of the so-called dexterous. Practically, it is advantageous to a man, and especially when he is a surgeon, to be born left-handed, for custom and prejudice compel him to exercise his right hand while nature inclines him to use the left on every possible occasion. In this way, yielding equally to both forces, he becomes ambidextrous. So far from being victims to awkwardness, &c., it will be found that kithogues are for the most part adepts in games wherein the hand takes a prominent part—such as cricket, racquets, billiards, and so on. No sooner does the cry "left hand" resound across the sward than the fielders prepare themselves for leather hunting; and, although he certainly does look uncouth, a sinistrous coachman may be trusted not to let his horses down. It cannot be denied that the complaints of the kithogues against philologists have in reality a genuine foundation. It is, therefore, high time that their sylleptic grievances should be remedied.

I am, Sirs, yours faithfully,

Dec. 22nd, 1896. KITHOGUE.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

V.—MANCHESTER.[1]

An Attack on the General Practitioners and a Defence of the Hospitals and the Consultants.

THE impression prevails that the general practitioner is the victim of hospital abuse, that his professional standard is lowered and his income very much affected by the competition of hospitals, which rob him of his patients. This, in a measure, is all true; but there are two sides to every case, and if the hospitals lay themselves open to criticism the general practitioner may be not altogether free from blame. It so happens that in commencing my inquiry at Manchester I heard more against the general practitioner than in his favour. Subsequently the arguments on the other side were brought forward, and I think the truth will best be attained by taking both in due order. My first visit was to a leading consulting surgeon of a large hospital. His opinion was very emphatic. The general practitioners were themselves the authors of much of the hospital abuse that prevailed. General practitioners were constantly sending well-to-do patients to the hospital. For instance, a person suffering from empyema was recommended to him the other

[2] THE LANCET, Dec. 19th, 1896, page 1173.
[3] THE LANCET, Aug. 3rd, 1895, page 273.
[4] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *continued*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; and (4 *continued*) Dec. 12th, 1896, Liverpool.

Hosted by Google

day. The medical man had a big bill against this patient, so big as to be unmanageable and he feared that he might not be paid at all, so this general practitioner sent the case to the hospital in the hope that the patient might be more rapidly cured and also have time to recover himself financially. The hospital surgeon or physician is thus, it is alleged, called upon to work gratuitously so as to enable the general practitioner to recover his fees from a fairly well-to-do patient. In this incident the secretary of the hospital refused to admit the patient unless he paid 10s. a week towards his maintenance. This constituted a small compensation for the hospital, but it was no compensation at all for the medical staff. The majority of in-patients admitted to the hospital were sent by medical men because they generally gave the preference to cases thus medically recommended. As a practical result the outcome amounted to this—that if the hospital occasionally robbed the general practitioner of a patient the general practitioner very frequently robbed the consultant of patients by sending them to the hospital. The consultant, however, must suffer quietly. He cannot complain, otherwise he would be boycotted by the general practitioners. Thus, as another case in point, my informant saw a little while ago at his hospital a woman who was suffering from a dermoid cyst of the ovary. The medical man who had attended her knew that she could afford to pay a consultant's fee and might have gone to the consulting surgeon's private operating home. The charge at such homes varies from three to six guineas a week. Perhaps an outlay of some £30 might have been necessary. The general practitioner fears that if he advises his patient to incur such expense his own bill will not be paid, therefore he writes a letter to a consulting surgeon and asks him to use his influence so that the patient may be admitted in the hospital. As the operating surgeons depend for their paying and better-class patients on the good will of the general practitioners they do not complain. If, however, one hospital more careful and scrupulous than is usually the case refuses to take the patient in, some other hospital will be less rigorous and then the general practitioner most inconsistently complains that there are too many hospitals. It is just because there are so many hospitals and because their rules of admission are somewhat lax that the general practitioner is able to utilise them to get himself out of a difficulty with regard to his patients and to prevent any of the money they are able to pay for medical advice going to anyone else but himself. At the hospital, where my informant acts as operating and visiting surgeon, the managing committee met to discuss the abolition of the recommendation system. Some general practitioners had objected that it made them lose time to obtain recommendations for those of their patients whom they wished to send to the hospital. They urged that if they sent their patients with a card that should suffice. The committee, however, objected that the hospital would then become a mere dumping-ground for old chronic cases and non-paying patients.

Calling subsequently on one of the visiting physicians of the Children's Hospital he declared that he had no knowledge of cases where general practitioners had sent patients to hospitals who could afford to pay for treatment in a private home. As a physician this grievance had not come under his notice, and it was much more likely to affect operating surgeons. A gentleman did, however, come to the hospital whom he knew to be in receipt of £5000 a year. He reproached this gentleman for seeking to abuse a charity, and the gentleman in question became one of his private patients, often paying five guinea fees. Undoubtedly there was considerable abuse among the out-patients, but this was rare among the in-patients. To his infinite regret it seemed to him that the profession, as a whole, was losing tone. Many medical men had introduced a shoppy element into their professional behaviour and practised "undercutting" and invented "tricks of trade." Thus in this very agitation against hospital abuse a selfish and sordid tone, he considered, prevailed that was damaging to the cause and humiliating to the profession. It seemed as if medical men were only concerned about their pockets. Let those who aimed only at a money result stick to business or trade and not invade the ranks of an honourable profession, which should strive after a much higher ideal. The public were interested in this matter of hospital abuse, and it was their interests rather than the sordid motives of medical men that should be pressed forward. Doubtless many persons who could afford to pay for medical advice went to the hospital. This story had been told, and told pretty often; but how many people were there who could not afford to pay for medical advice, and yet, by dint of many and painful sacrifices, did pay rather than go to the hospital? The general practitioner profited perhaps as much from this class as he lost from the other and meaner class, though very little was heard about it. The general practitioner complained of the hospitals, of the consultants, and of the specialists; but what did he do when he fell ill himself or any member of his family fell ill? Did he call in a general practitioner or trust to his own treatment? On the contrary, and often only for trifling ailments, he sent for the consultant or specialist. In protesting against every institution that deprived him of a patient, that is to say, of a fee, the general practitioner was too apt to forget that his patient's welfare had also to be considered. It was the shoppy element in the hospitals, among the consultants, the specialists, and the general practitioners that constituted the foundation of the present grievances. We had to drive the spirit of commercialism away and revive the higher professional ideals, treat every patient as we should wish to be treated ourselves if we were patients, and not allow sordid motives to exercise any influence. There might then be less complaints about patients going to consultants, specialists, or even hospitals. Thus the visiting physician to the Children's Hospital. Of course, the general practitioner may retort that when a medical man has reached the highest grades of the profession it is easy to indulge in these fine sentiments. Sitting in a luxurious consulting-room, awaiting, with the certainty of realisation, the receipt of numerous guinea and of occasional five-guinea fees, it involves no great effort or trying self-sacrifice to proclaim the above altruistic principles. Besides, though undoubtedly beautiful and true, it so happens that this little sermon promotes, under the mantle of moral teaching, the financial interests of the consultant.

Other consultants on whom I called likewise put their own case and that of the hospitals very forcibly before me and were unsparing in their criticisms of the general practitioner. One of the most prominent operating surgeons of Manchester declared that he was convinced that many general practitioners drove their patients to the hospitals by objecting to call in a consultant. An anxious patient might suggest the advisability of such a course, but the general practitioner would angrily inquire whether the patient could afford to pay two guineas. The patient, in despair, went to the hospital, where he obtained advice from the consultant for nothing. Many patients required to be under the temporary care of a consultant, but could not afford to pay a guinea a visit. If, to meet these cases, the consultant reduced his fee to half a guinea the general practitioners immediately organised a boycott against the consultant. So great was the antagonism between the general practitioner and the consultant that the former not unfrequently allowed his patients to continue suffering indefinitely rather than allow them to go to a consultant. Not long ago a Manchester general practitioner complained because a consultant had in a special case taken a half-guinea fee. Practitioners also complained that the address of specialists was given to patients by the secretaries or clerks of hospitals. Patients who can afford to pay come to the hospitals to obtain these addresses because, it is alleged, their ordinary medical attendant is so much opposed to seeking a consultant's advice that he will not himself give the address. It may happen that persons living in neighbouring towns are under the care of their family medical man for several months and no progress is made. Nevertheless, the local practitioner sneers at the idea of a consultation and the patient is afraid to ask his medical man or the name and address of a consultant. Consequently when the patient's patience is exhausted he takes the train and goes to Manchester. On arriving he asks the way to the infirmary. He has no intention to defraud that charitable institution, but knows that there he will obtain the best advice. The secretary inquires as to the applicant's wage limit and expostulates when he finds that he has ample means; but the applicant replies that he came fully prepared to pay, all he wanted was the best advice. The secretary then gives the addresses of the members of the hospital staff. The very stubbornness of the general practitioner in refusing extra help or a consultation causes the patient to find out that this is necessary. Then the patient comes and is treated either at the hospital or, if he can afford to pay, as a private patient of a consultant. On returning to his home he naturally spreads the news of

Hosted by Google

his recovery and the tendency to resort to specialists or consultants is thus becoming more and more general. The great difficulty is with that numerous class of patients who can afford to pay but cannot pay guinea fees. There it is that hospital abuse arises. They are dissatisfied with the general practitioner and cannot afford to go to the consultant, yet the latter dare not reduce his guinea fee to meet the financial position of this numerous class. The consulting surgeon with whom I was discussing this matter expressed his conviction that he could triple his income if, during two days in the week, he were able to give consultations for 5s. fees and this would prevent much of the hospital abuse. It was his conviction that many patients died prematurely because they could not afford the guinea fee for the consultant and did not like to go to the hospital. In his practice he had seen many cases, notably of cancer, which had come to him only in the last extremity when it was too late to do any good. Such patients died prematurely because they could afford to pay 3s. 6d. fees. Had they been poorer they would have come to the hospital sooner and their lives would have been saved or at least prolonged. Hospital abuse was not so grave as the general practitioners made out; but it was the old story of the two men who quarrelled as to who should milk the cow. While the general practitioner and the consultant were disputing as to what should be done with regard to the patient who could not afford a guinea, but would gladly give 5s., the patient took himself off to the hospital, with the result that both general practitioner and consultant lost their fees.

In almost the same terms as those employed by the consulting physician I had previously seen, the consulting surgeon I was now interviewing laughingly remarked that when the general practitioner's wife was ill telegrams came pouring down upon the specialists. They were to take the train, they were to come at once; and, after all, as often as not, it turned out to be quite a trivial case. In a more earnest tone he lamented that general practitioners too often failed to treat their patients as they would like to be treated themselves. Rows and commotions arose because patients were not always advised to their best interests. If a general practitioner, after two or three weeks' attendance on a special disease, found that there was no improvement the patient should be sent to the hospital with a note from his medical attendant demanding not general treatment, but advice. At the same time, if this were rendered too easy patients who could afford to pay guinea fees for the same advice would be sent to the hospital, and this would not be fair to the consultant. There was no disguising the truth, he said, that the ordinary medical qualifications did not suffice for special cases. This was best proved by the fact that general practitioners, when they were themselves afflicted, resorted to specialists. After all, patients were not made for the medical man, but the medical man was made for the patients. The best medical man was he who freely transferred his own patients to better men, if necessary. It was preposterous for a medical man to imagine that he was competent to do everything. But in speaking of better men it did not follow that the consultant was superior to the general practitioner. My informant, though considered one of the most prominent consulting and operating surgeons of the town, frankly admitted that he would be quite incapable of doing a general practitioner's work. He had not put up a fracture for the last eighteen years or more and would not like to be called upon to reduce a dislocation. He would consider it little short of a crime if he attempted to remove a cataract. Many of his patients had sufficient confidence to let him attempt any sort of operation, but thought none the worse of him when he refused a fifty-guinea fee and sent them to a better man. The public were not so ignorant and could understand that a man who was skilled in removing an ovarian tumour might be less successful in operating upon the eye. At the hospital with which he was connected there was at the present moment a woman who was married and the mother of children. The income of the family amounted to £5 a week. The operation in this case would cost £100. The general practitioner who attended this family had not the special skill necessary to perform this operation, and a family with £5 a week could not be expected to pay a £100 fee to a consultant. It was no use complaining because this woman had come to the hospital. Patients with private means did not generally come to the hospital till they had tried other means. After all, inquiry should be made of the public as to what the patients themselves have to say and how they explain their conduct. It was no pleasant matter to pay even half-crown fees throughout a long and wearisome illness and feel that there were at the hospital specialists who would, in all probability, effect a cure in a much shorter time.

Such were some of the arguments adduced by consultants and members of the staffs of the Manchester hospitals. It now remains to be seen what measures are taken at the hospitals to prevent abuse and what the general practitioners have to say on the subject. I have given the views of the consultants first, but no one must prejudge the case. Before my readers make up their minds on the subject of hospital abuse at Manchester they must hear the other side.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Inspectors' Association.

A MEETING of the Lancashire and Cheshire Branch of the Sanitary Inspectors' Association was held on Saturday, Dec. 19th, at the Manchester Technical School. The members first inspected a number of technical appliances lent by the school authorities and were afterwards addressed by Mr. J. Ratcliffe, chief lecturer on sanitary science at the Manchester Technical School, on a Sanitary Inspector's Duty with regard to House and Drainage Inspection. He said that some authorities, under the impression that no skill was required, "were in the habit of choosing for such places policemen, railway porters, unsuccessful tradesmen, or men who had failed in every other walk of life." He said that the sanitary inspector was the guardian of the public health, and he thought had reform in this matter in his own hand. Above all things, he must have a good knowledge of the scientific portion of his work and be ready to put it in practice. "These were the men who would be dreaded by the jerry-builder and the owner of old-fashioned property." After impressing on his audience the necessity of a close acquaintance with natural laws he explained the main principles of sanitation, illustrating his subject with lantern views and diagrams. It is probably true, as the lecturer thought, that the sanitary inspector is much undervalued by the general public whom he serves, which is not to be wondered at if the authorities appoint ignorant, unskilled men. Considering the importance of his work, and the fact that much of it is concerned with what is usually out of sight, it is necessary that there should be not only the requisite knowledge but character and high principle. Manchester, it is only fair to say, does not come in the category of "certain authorities," for great care is taken to obtain the services of efficient, trustworthy men.

Manchester Geological Society.

On the 18th inst. an interesting paper by Messrs. Barnes and Holroyd was read at a meeting of the Manchester Geological Society on Some Effects of High Pressure on Decomposing Vegetable Matter. The experiments were first suggested by Wheelton Hind of Stoke-on-Trent. The first was made with freshly cut moist peat, which was placed in an iron cylinder 3 in. deep and 3 in. in diameter, the wall being 2½ in. thick. An iron ram was placed on it having a diameter just sufficient to allow of its passing smoothly into the cell. Hydraulic pressure was applied until it had reached about one ton to the square inch, when the iron cell burst, owing probably to the incompressibility of the water contained in the peat. The broken cell was strengthened and another attempt was made on thoroughly desiccated peat, which was subjected to a pressure of twelve tons to the square inch, and at this it was allowed to remain for twelve or fourteen hours. When the peat was withdrawn it had decreased to about one-fifth of its original bulk, and at the periphery, where it had been in contact with the interior of the cylinder, it had a shining black appearance very much resembling coal. "When broken it showed that in a great measure the fibrous vegetable structure was much reduced or destroyed and the mass had a distinctly lignitic appearance." Its specific gravity was found by calculation to be 1·5, that of coal being from 1·2 to 1·8. In another experiment dried autumn leaves of ash, sycamore, oak, elm,

Hosted by Google

and hawthorn were exposed to a pressure of 20 tons to the square inch. The margin of the compressed mass presented the same coaly appearance, with shining particles on the upper and lower surfaces, and its specific gravity was 1·42 An experiment with sycamore leaves gave similar results. In another experiment with peat, at a still greater pressure, the degree of mineralisation at the point of contact with the iron was still greater. When burnt the compressed peat behaved very much in the same way as coal. It did not ignite at once, "but after a short time burst into flame, emitting streams of volatile and inflammable gas." The deduction from the various experiments was that pressure must have played a very important part in the changes from vegetable decomposing matter to mineralised coal, which, perhaps, scarcely needed showing; but, nevertheless, the demonstration was most interesting.

Manchester and Salford Sick Poor and Private Nursing Institution.

The annual meeting of the above institution was held on Friday afternoon in the Lord Mayor's parlour in the Manchester town hall. The report states that the object of the institution was "to provide throughout the length and breadth of the city wherever sickness and poverty were found together the careful ministrations of the district nurse." There are 25 thoroughly trained and efficient private nurses and 47 district nurses. During the year 8233 patients had been attended and 210,500 visits paid by the nurses. But, as we hear so often, "the general financial state of the institution gave rise to feelings of anxiety," for during the year there had been a considerable excess of expenditure over income, and but for a legacy of £1000 from the late Mr. Berry, about £400 of which "had been absorbed in meeting the deficiency," and, as Mr. W. Mather said, "without the bequests received, they would not have been able to go on." He suggested that those who employed the private nurses should contribute to the general fund "in however small a degree." During the year 1200 home patients of the various hospitals had been tended by the district nurses, who had paid 31,000 visits "under the direction of the hospital medical staffs." Others had been nursed for the medical officers of the provident dispensaries or for private practitioners. Surely more liberal support should be given to this useful society.

The Proposed Rebuilding of the Royal Infirmary: Result of the Poll of Trustees.

The votes of the trustees of the Manchester Royal Infirmary on the question of a rebuilding and extension on the site in Piccadilly, in accordance with the plan submitted by the Grand Committee, were counted on Wednesday, Dec. 23rd, 1896. The number of voting papers issued was 1349, and of these 853 were returned. The counting took place yesterday morning, Sir Frank Forbes Adam and Mr. E. S. Heywood being scrutineers representing those in favour of the motion, and Sir John Harwood and the town clerk (Mr. W. H. Talbot) acting in the same capacity for those against it. The result of the poll was declared as follows: For the motion that the infirmary should be rebuilt on its present site, 449; against, 403. The result will be submitted to a special meeting of trustees to be held in the middle of January.

Dec. 24th, 1896.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Christmas at the Hospitals.

THE usual festivities of the season lacked no enthusiasm this year in the efforts to make the time appreciated by the inmates of the various hospitals. At the General Hospital an attraction was secured by the presence of Mrs. Chamberlain, who kindly gave away the toys from a huge Christmas tree, to the delight of the younger inmates. The older ones were treated to songs and music by various members of the staff, and the occasion was an enjoyable one in every respect. At the Children's Hospital Father Christmas distributed toys and gifts to a number of children amid much excitement and pleasure. An amusing incident in connexion with the Jaffray Hospital shows that sometimes even the ever watchful press slumbers. That branch of the General Hospital has been closed for some months for cleaning and repairs and still remains untenanted, yet in the descriptive narrative of a local paper the inmates were regaled with roast beef and plum puddings and spent a happy and enjoyable Christmas-time. Truly imagination plays a prominent part in the minds of some reporters, excusable, perhaps, by the good intentions of the season.

The Queen's Hospital.

The resignation of Mr. Wilders, one of the surgeons of this institution has been received with much regret. For nearly forty years Mr. Wilders has been connected with the hospital, first as assistant house surgeon and for twenty-eight years as senior officer. In the words of the chairman of the hospital: "During that time he has served the hospital with fidelity and zeal, ever working in harmony with his professional and lay colleagues." The grateful thanks of the authorities were accorded to him unanimously with the hope that his long illness would eventuate in recovery and that his life would long be spared.

Neglect of Children.

Too common an occurrence in the midst of our boasted civilisation is the deplorable neglect of the youngest branches of the community. The Society for the Prevention of Cruelty to Children does a good work in the city by occasionally prosecuting in the most flagrant cases. An instance lately occurred in which a mother who is stated to have borne sixteen children in nineteen years grossly abused the attributes of maternity. Four of the children were insured for an aggregate sum of £22 10*s*. One of them died after great neglect. The mother, of drunken habits, was seldom in a fit state to attend to the wants of the youngest; and in a deplorable condition of disease and dirt one of them died. The magistrates marked their disapproval of her conduct by a term of three months' imprisonment, during which period, no doubt, time for reflection and reformation will be afforded to this unfortunate victim of the great destroyer drink.

Dec. 29th, 1896.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Outbreak of Swine Fever at Ruinhill.

SWINE FEVER has broken out at the County Asylum at Rainhill. A new order with regard to the sale of swine comes into operation on Jan. 1st, which will have the effect of preventing the public sales of fat swine without permission, and for which licences will have to be obtained. Also, where swine have been on premises twenty-eight days a sale of store swine will not be permitted.

Liverpool Medical Institution.

The following nominations have been made by the Council of this society, subject to confirmation at the annual meeting, which will be held on Jan. 14th:—Vice-Presidents: Dr. A. C. E. Harris and Dr. Karl Grossmann. Hon. Treasurer: Dr. James Armstrong. Hon. Librarian: Dr. T. R. Bradshaw. Dr. Harris's period of office as President of the Birkenhead Medical Society has recently terminated, a post which he filled in a highly creditable manner. The President of the Liverpool Medical Institution (Dr. Caton) will deliver his inaugural address on Jan. 7th. The subject of the address will be the Results of Recent Excavations at Epidaurus and Athens bearing on Medical Treatment as carried out in the Temples of Asclepius, with lantern illustrations. The presidential address will be followed by a smoking concert.

Liverpool Royal Infirmary.

It is an open secret that at the approaching annual meeting of the trustees of the Royal Infirmary a vacancy on the senior honorary staff will be declared.

Christmas at the Liverpool Hospitals.

At the Royal Infirmary the wards and the chapel were tastefully decorated with evergreens, sent by kind friends for the occasion. Roast beef and plum pudding were served at mid-day to the patients in the wards; tobacco was also distributed to smokers. Presents of fruit, plants, and toys, besides articles of clothing, have been received from friends of the institution. On Christmas evening, carols were sung in each of the wards under the direction of Dr. Livsey, honorary organist to the chapel, who accompanied by means of a harmonium. The wards were visited during the day by

Hosted by Google

several members of the Committee and their friends. At the Northern, Royal Southern, Children's and Workhouse Hospitals the festivities were on similar lines.

Dec. 29th, 1896.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Memorial to the late Mr. G. E. Alford of Weston-super-Mare.

THE formal opening of the "Alford Memorial Ward," furnished with funds raised by friends and patients of the late Mr. G. E. Alford, M.R.C.S. Eng., L.R.C.P. Lond., who had been for several years an honorary surgeon to the institution, took place on Dec. 23rd. The ward contains an excellent portrait of Mr. Alford and will shortly be provided with a memorial tablet and with a stained window depicting St. Luke, the physician. There was a large attendance, and the President (Mr. T. Mullens, J.P.) in declaring the ward open said that Mr. Alford was a gentleman who had done noble work in the improving of the hospital, and it had been thought that the best way of testifying their appreciation of his efforts would be in the forming of a memorial ward in the hospital in which he had shown so much interest.

The New Hospital for Newport (Mon.).

Up to the present the promises of support to the new hospital at Newport amount to about £8000, and this, in addition to the gift of Dr. A. Garrod Thomas, makes altogether about £13,000.

Isolation Hospitals in Glamorganshire.

At the meeting of the Glamorganshire County Council the solation hospitals sub-committee recommended that notice should be given to the Oystermouth, Gower, Briton Ferry, Caerphilly, Glyncornwg, Pontypridd, and Maesteg District Councils that they must adopt definite plans for isolation hospital accommodation by March 1st, or the council will proceed to make compulsory orders.

The Preservation of Dartmoor.

At a meeting of the Plymouth borough council, held on Dec. 14th, the question of the acquisition of Dartmoor by the county of Devon in order to prevent further encroachments was discussed. This scheme, which was submitted by the Dartmoor Preservation Association, was unanimously approved of, and the council pledged itself to bear its fair share of the cost of purchasing 130,000 acres of Dartmoor from the Duchy of Cornwall, provided that the county authorities have power to preserve all objects of archæological and antiquarian interest and the indigenous plants and animals. The other Devonshire authorities have also promised their support to the scheme.

Death of Mr. G. F. Schacht of Clifton.

Mr. George Frederick Schacht, the well-known chemist of Clifton, died suddenly on Dec. 26th. Mr. Schacht, who was seventy-three years of age, had been for twenty-five years a member of the council of the Pharmaceutical Society, and on his retirement from that office last autumn was presented with an address acknowledging the useful work he had done for the society. He had been vice-chairman of the society and also a member of the examining body, pharmaceutical education being a matter in which he was greatly interested. He was honorary treasurer of Bristol University College, and at the recent annual meeting of the governors he spoke highly of the chemical work done at that institution.

Dec. 29th, 1896.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh.

THE following are the numbers of the students who attended the several classes of systematic lectures in the Faculty of Medicine in Edinburgh University during winter and summer sessions, beginning in October, 1895, and ending in July, 1896: Chemistry, 281; botany, 228; zoology, 215; physics, 267; anatomy, 213; physiology, 443; surgery, 213; materia medica, 246; practice of physic, 230; midwifery, 178; medical jurisprudence, 174; mental diseases, 99; and ophthalmic surgery, 55.

Clinical Demonstrations to Medical Practitioners.

The physicians and surgeons of the Glasgow Royal Infirmary, with the consent of the managers, have arranged to give during the winter and summer sessions weekly demonstrations of cases in the wards, open to all members of the profession who care to attend. It is proposed that every Friday afternoon one of the physicians or one of the surgeons shall be responsible for the demonstration, and the members of the staff have unanimously assented to the arrangements. There can be little doubt that these demonstrations will be most valuable to practitioners, giving them opportunities to renew their acquaintance with hospital methods and to become practically familiar with the more recent improvements in diagnosis and treatment. Both the managers and the staff are to be congratulated on a departure which indicates a keen perception of the duties and opportunities attached to those responsible for the policy of the hospitals as centres for clinical instruction. And it can only be for the public benefit that the practitioner shall be encouraged to continue to some extent his hospital attendance even after entering on private practice. The first demonstration is to be given by Mr. Henry E. Clark, senior surgeon to the infirmary, on Friday afternoon, Jan. 8th, at four o'clock.

Glasgow University.

The register of the General Council for the year 1897 has now been made up. It shows the addition of 189 new members, whilst 106 names have been removed, making a net gain of 83. The present total is 5406. The Christmas holidays commenced on Dec. 21st, and are to be continued until Jan. 5th, when the classes will be resumed.

Police Appointment.

The sub-committee of the Corporation appointed to deal with the vacancy in the casualty surgeonship of the Northern police district, Glasgow, have decided to recommend the election of Mr. R. Bain Lothian, M.B., C.M. Glasg. The salary is £50 per annum and there were seven other candidates.

New Fever Hospital for Stirling County.

The new hospital erected near Camelon by the Eastern District Committee of the County Council was opened on Dec. 22nd Mr. Geo. Ure of Wheatlands presiding at the formal ceremony. The cost of the hospital has been £7500. It is arranged in four blocks and includes, in addition to the usual accommodation, observation wards for the admission of doubtful and suspicious cases. After the opening ceremony the committee entertained the visitors to luncheon.

Professor Gairdner on Samaritan Hospitals.

The recent institution in Glasgow of a hospital for diseases of women, calling itself the "Samaritan" Hospital, has, it appears, led to some confusion in the minds of the benevolent in consequence of the fact that for many years there has existed in connexion with the Western Infirmary a Samaritan society, having for its object the supply of clothing and other necessaries to patients on leaving the infirmary. To prevent misconception the President of the Samaritan Society (Mrs. Berry) wrote to the newspapers explaining the position. This led to some correspondence, amidst which appeared a letter from Professor Gairdner containing the following passages: "Without prejudice as regards any particular institution in Glasgow or elsewhere which calls itself a 'Samaritan' hospital allow me to ask ..... if there is anywhere any good authority in Scripture or out of it, even the smallest grain of common sense or etymological propriety, in a special hospital for women appropriating to itself distinctively the name and credit of the 'Good Samaritan'—for I suppose it is the Good Samaritan and not the Woman of Samaria or the ungenial and bigoted type that we read of, and to which the Good Samaritan was a brilliant exception, that is here in question? The Samaritan Society of the Western Infirmary does well to be so called because its work is purely good Samaritan work on the strictest lines of the great original in the parable and not limited in its motive by any consideration of age and sex and condition. But when one or more able and enterprising gynæcologists contrive, with much canvassing, bazaars, &c., to have a special hospital erected for the diseases of women, we may even approve their object and are not to be held as in any way assailing their enterprise if we ask, What has the Good Samaritan, or any other Samaritan that we know about, specially and distinctively to do with gynæcology? ..... The Woman of Samaria, we are told, had five

Hosted by Google

husbands; but notwithstanding this undue allowance of male support and protection there is not a word or a hint of her having ever been in the hands of a 'gynæcologist.' ..... It will be difficult, I suspect, to turn the Woman of Samaria to the account of gynæcology. Whence, then, the name? The promoters of 'Samaritan' hospitals owe an explanation to the public on this subject."

Aberdeen University.

On Dec. 28th there was presented to Aberdeen University Court the portrait (painted by Sir George Reid, P.R.S.A.) of Mr. David Rennet, LL.D., a successful private teacher of mathematics and natural physiology in Aberdeen. At the same time a replica was presented to Dr. Rennet. Subscriptions came largely from Dr. Rennet's old pupils, and the balance of the fund will be handed to the University Court for the foundation of a gold medal, to be awarded annually for distinction in some branch of mathematical study.

Aberdeen Hospital for Incurables.

During 1896 16 patients were admitted to Morningfield Hospital, 12 died, and 3 were discharged, leaving 67 in the institution at the close of the year. The ordinary expenditure was £1727, being £383 11*s.* 3*d.* above the ordinary income. Legacies produced £387 14*s.* 10*d.*, leaving a small balance in hand. Part of the hospital fees duty has been redeemed by a payment of £490 out of capital.

Aberdeen Royal Infirmary.

In reminding the citizens that Sunday, Jan. 3rd, is Hospital Sunday in Aberdeen, the directors state that the expenditure for the current year may be set down as £8000 and that the outlay grows with the increase of buildings. When the new medical block is opened in May next, it is stated, the infirmary will, as regards comfort and general equipment for the treatment of the sick and injured, be one of the finest hospitals in the United Kingdom. At Jan. 1st last 161 patients remained in the hospital. During this year to Dec. 23rd 1929 patients were admitted, making a total of 2090, of whom 979 recovered, 603 had improved, 196 had been discharged as unfit, at desire, &c.; 152 had died, and 160 remained in the infirmary. In addition 5399 casual cases had been treated. Dr. P. Blaikie Smith has, owing to the state of his health, resigned his post as one of theordinary physicians and has been appointed a consulting physician.

Dec. 30th, 1896.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Memorial Statue of the late Surgeon-Major Parke.

THE event of last week in Dublin was the ceremony of the unveiling of the statue of the late Surgeon-Major Parke, the companion and friend of Stanley in Darkest Africa. The statue, which is of bronze, is placed on a stone pediment in the Leinster Lawn, an admirable site which contains already a handsome bronze allegorical group erected in memory of the late Prince Consort, and a statue of the late William Dungan, who founded the Irish Industrial Exhibition of 1853. There was a distinguished and representative assembly present, the military and medical professions being, of course, well represented. After Dr. Wheeler, as one of the former teachers of Surgeon-Major Parke, had delivered a brief panegyric of the deceased, Field-Marshal Lord Roberts, the Commander-in-Chief in Ireland, said that although he had not had the honour of knowing the late Surgeon-Major Parke, he had felt a great admiration for that officer's character, and was proud to remember that he belonged to the Army Medical Department. The statue, which is an admirable likeness, was then unveiled and exhibited to the view of a large and distinguished audience.

Death of Sir George Owens, M.D.

Sir George Owens, M.D. Glasg., died at his residence in Dublin upon Dec. 29th. He took the degree of M.D. at Glasgow University in 1850. In 1876 he was Lord Mayor of Dublin and was knighted during his year of office. In 1881 he filled the office of High Sheriff.

The Richmond Lunatic Asylum.

The epidemic of beri-beri in this institution does not seem to have undergone much abatement. Mr. O'Conor Donelan, the acting resident medical superintendent, reported at the last meeting of the board of governors that the number of cases had reached 113, but that there was a decline in the number of fresh seizures during the last few weeks. Arrangements are at last being made to remedy the overcrowded state of the asylum, and block No. 1 of the temporary buildings at Portrane is now finished and ready for occupation. The cost of this, with the two other blocks now in course of erection, has been estimated at £10,900. Dr. Courtenay, inspector of the Board of Control, suggested for the consideration of the board of governors that it would be advisable, instead of concrete houses, to build cottages which might, after the construction of the asylum at Portrane, be used as residences for the attendants. A patient of the Richmond Asylum named Cluskey was recently—Dec. 21st—returned for trial on a charge of having murdered another inmate by striking him on the head with the iron grating of a sewer trap. The injured man was brought to Jervis-street Hospital, where it became necessary to trephine his skull, after which he improved so much that he was able to return to the asylum. An abscess ultimately formed in his brain and proved fatal.

Mercer's Hospital.

The board of governors of this hospital, as will be remembered, adopted some months ago the very unusual course of requesting the resignation of all the members of their medical staff. It is said that one medical man, fearing that he would not be re-elected, refused to obey the request and legal proceedings seemed at one time imminent. It is now, however, stated that a conference between the board of governors and the medical staff has been arranged to take place about the middle of January.

The New Belfast Hospital.

Dr. W. A. McKeown, who is surgeon to the Ulster Eye, Ear, and Throat Hospital, at the annual meeting of that institution, spoke of the great advantage the new general hospital would be to the Belfast Medical School, and quoted some statistics of great importance as coming from one who is an original senator of the Royal University of Ireland and a member of the Medical Committee of that body. The four institutions in Ireland specially connected with the Royal University were Queen's College, Belfast, Queen's College, Cork, Queen's College, Galway, and the Catholic University School of Medicine, Dublin. From an official return he found that the respective numbers of medical students sent up from these institutions in 1895 were as follows:—Queen's College, Belfast, 205; Queen's College, Cork, 113; Queen's College, Galway, 44; and the Catholic University, 93; so that the Belfast School of Medicine supplied nearly as many as the other three schools put together—205, as against 250. Belfast was, indeed, as regards these institutions, the predominant partner, and hence the necessity for good facilities for training the students. The 205 students do not, however, by any means represent the full strength of the Belfast Medical School, as many others went to the licensing bodies in Scotland. These figures also demonstrate, I may add, another fact that Belfast is not at all fairly represented on the examining boards of the Royal University. To give an example, at the M.B. board of the Royal University there are twelve examiners, and of these only two come from the Belfast School of Medicine, which, as Dr. McKeown points out, sends nearly as many medical students as the other three schools put together.

Prevention of the Spread of Infectious Diseases.

At the Londonderry Petty Sessions, on Dec. 28th, a military lieutenant residing outside Ebrington Barracks was summoned by the executive sanitary officer and fined 2*s.* 6*d.* and £1 13*s.* 8*d.* costs for allowing his son to attend school, contrary to the provisions of the Public Health Act, within a fortnight of the date on which it was certified he had scarlet fever.

Health of Belfast.

At the present time there is a great deal of illness in Belfast, especially scarlet fever and influenza. Some of the public schools have had to be closed owing to the former, and the latter is very widespread, many children being attacked in this epidemic. In the present outbreak of influenza throat complications are common and occasional rashes (making the diagnosis difficult as between influenza and scarlet fever)

Hosted by Google

are seen, but no desquamation follows, and in all cases of the disease there is the well-marked after-depression.

Ulster Eye, Ear, and Throat Hospital.

At the annual meeting of this hospital, held on Dec. 22nd, it was reported that during the year there were 1493 extern and 235 intern patients. The total receipts of the hospital from all sources were £610 10*s.* 10*d.* and the disbursements £609 17*s.* 11*d.*

Dec. 31st, 1896.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The late Emile Du Bois-Reymond.

ON Dec. 26th the University of Berlin lost one of its oldest and most valued members, Emile du Bois-Reymond, Ordinary Professor of Physiology, Director of the Physiological Institute, and Honorary Secretary of the Royal Academy of Sciences. It was by the labours of Helmholtz, Virchow, and Du Bois-Reymond that the claim of medical men to have their special subject reckoned among the sciences was first vindicated in a conclusive and satisfactory manner, and of these three, to whom we owe so much, Professor Virchow is now the sole survivor. The sorrowful event was not unexpected either by the friends of the deceased or his students, as he had for a considerable time been suffering from cardiac failure, which eventually compelled him to cease lecturing last summer, but he hoped to be able to resume his work, and therefore did not seek to be relieved from the duties of his appointment. The principal points in his personal history, considered apart from his scientific investigations, may be stated in a few lines. His father was a native of the canton of Neufchâtel in Switzerland, but came to reside in Berlin before the birth of his son, which took place in that city in 1818. Du Bois-Reymond spent almost the whole of his life in Berlin. His medical curriculum occupied him from 1837 to 1843. He became assistant at the Anatomical Institute in 1844, *privat-docent* in 1846, and extraordinary professor in 1856; in 1858 he was promoted to be ordinary professor. His name is, and always will be, associated with one branch of physiological observation and research—namely, the special physiology of muscles and nerves, a field which before his time was almost unexplored. His attention was first directed to these questions in 1841, when Professor Johannes Müller, observing the bent of his mind towards original inquiry, suggested to him a critical examination of the observations made by Matteucci on the electrical phenomena presented by animals. The advice was immediately followed, and the researches then commenced were destined to occupy him during the remainder of his life. So engrossed did he become in these pursuits that, as he himself used to say, frogs and the multiplicator for studying electric currents were his only companions during many years. His first publications were too aphoristic to find favour with the scientific world, but his "Researches on Animal Electricity," which appeared in 1848 and 1849, brought him at once to the front. His discovery of the existence of electric phenomena in connexion with muscles and nerves inaugurated a long series of animated discussions, which are occasionally revived even now. His great celebrity, however, was mainly due to his having been one of the foremost protagonists in the struggle between materialism and vitalism. In the beginning of his career vitalism was still a recognised theory in natural science, but jointly with the brothers Weber, Helmholtz, Meyer, and other eminent men he was one of the first to maintain that all the processes of life depend exclusively on those of physics and chemistry. This he held to be an established fact, not admitting of any doubt or question, and when not long ago a modification of the old vitalistic theory reappeared under the name of Neo-vitalism, suggested by Professor Rindfleisch and others, he at once took the field against what he deemed to be false opinions. One of his last communications to the Royal Academy of Sciences was a reply to an address delivered by Professor Rindfleisch at Frankfort before the Association of German naturalists and medical men, but he did not go so far as to imagine that all problems must be regarded from the point of view of natural science exclusively. His essays on the Limits of Knowledge and on the Seven Mysteries of the World, in which he conscientiously made the avowal "Ignorabimus," excited the hostility of the more "advanced" group of thinkers, especially those of the Jena school. Du Bois-Reymond was possessed of great natural gifts both as a teacher and a speaker. His hearers were charmed both by the easy clearness of his style and the finished polish of his phrasing—a combination of qualities not always found in a German professor, and perhaps partly attributable to his French origin. This serves to explain the well-known fact that not only were his professorial lectures on physiology most regularly attended by the students from the beginning to the end of the session, but his popular addresses on topics of general interest, delivered once a week in the *auditorium maximum* of the University, always drew large audiences including both sexes and all classes of society. Physiological teaching and research in Berlin are indebted to him for the providing of an establishment worthy of the science so important as one of the foundations of medical knowledge. Visitors to the Quartier Latin of Berlin will be struck by the palatial appearance of the new Physiological Institute, built and fitted in precise accordance with his ideas and provided with every requisite. This is the place where Du Bois-Reymond and his pupils, the late Professor Baumann (not long since deceased), Dr. Sachs, Professor Fritsch, Professor Krenacker, Professor Goltz, and many others, have contributed so much to the development of physiology and the progress of natural science.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Brain of a Brigand.

THE literary "hit" of the month is Professor Cesare Lombroso's article in the *Nuova Antologia* on the brain of Tiburzi, the brigand chief who for nearly twenty-five years levied contributions on Central Italy with a boldness and success explained only by his having been no merely vulgar malefactor, but in his way a hero of romance, a "rectifier of the financial frontier" between rich and poor, and as far removed from meanness as he was superior to moral scruple. The whole countryside was devoted to him: no informant could be found to guide the agents of the law; no jury could be "packed" even if he ever fell into the hands of "justice." At last he met a brigand's death in open conflict with the *carabinieri*, and at Professor Lombroso's request his brain was preserved and duly subjected to anthropological analysis. It is Professor Lombroso's report and commentary on this that give the article in the *Nuova Antologia* its fascinating interest, to say nothing of the fact that the occasion proved a welcome one for him to "put himself right" with the Russian and German critics who at the last Anthropological Congress accused him of attaching to physical conformation a significance properly shared with early associations and moral environment. Tiburzi's brain, he admits, presented nothing abnormal; every organ was duly developed, the hands especially being beautifully proportioned, while, as to his physiognomy, it strongly resembled that of one of the ablest and mildest of recent Italian statesmen, his Excellency Cesare Correnti, some time Minister of Public Instruction! This finding seems awkward for the upholder of the "uomo delinquente" or "criminel-né"; but Professor Lombroso is quite equal to the dilemma. Unable to bring home to the deceased brigand any transmitted taint, his father and mother having been "brave persone," he elevates him into a social enthusiast impressed with the unequal distribution of fortune's favours—one who in an age more propitious for such types would have rivalled a Sforza, a Piccinino, or a Medici delle Bande Nere. As it was he pursued his *métier* in his little world with an intelligence, an administrative—nay strategic—ability, a temperance, and a faculty of inhibition quite foreign to the "criminel-né," qualities that relegate him to a category for which Professor Lombroso has to coin a term—the "criminaloid"—a man, that is to say, who from motives not bad in themselves (nay, to some extent laudable) becomes a social pariah and, in legal technicality, an outlaw. The whole article has even more interest for the romancist than for the professional student, and may be recommended for artistic purposes to a man of letters who combines both capacities—for instance, Dr. Conan Doyle.

Precautions against the Pestis Bubonica.

Dr. Baccelli presided at an "urgency meeting" of the Consiglio Superiore di Sanità held the other day to approve prophylactic measures against the importation from East Indian ports of the pestis bubonica. All the members residing in Rome, to the number of fourteen, were in attendance, and the reporters were Signor Comandù, member of the Chamber of Deputies, and Dr. Panizza. After due consideration of the precautions taken by the Minister of the Interior on the first announcement of the plague from Bombay the council had to weigh objections advanced in the interests of commerce, which, it was represented, might be compromised by the rigid enforcement of the said precautions. The conclusion come to was a unanimous approval of what the Minister of the Interior had already done, and seeing that the plague in India shows small sign of abating the council further empowered the two reporters and the "Capo-Divisione della Sanità" to recommend to the Minister such supplementary precautions as the future course of the epidemic might necessitate.

Honours to Italian Medicine.

Scientific amenities are "in the air." The Royal Society of London had scarcely awarded its Darwin medal to Professor Grassi for his researches in confirmation of the law of evolution, when the Académie Française conferred on Dr. Francesco Todaro, Professor of Anatomy in the Roman School, its gold medal in recognition of his anatomical and embryological work, and of the very important part he has borne in the resuscitation of morphological studies in Italy during the last thirty years.

Death of Professor Luigi Calori.

In Italy death has, on the whole, been sparing of men of light and leading in the profession during 1896, but among those who have "gone over to the majority" Bologna has to deplore her able and accomplished Professor of Anatomy, Dr. Luigi Calori, member of the Academy of Sciences and corresponding fellow of numerous other scientific bodies, Italian and foreign. To the last he kept up his interest in the nature study in which he was early proficient, and, while an admirable teacher of his special subject, he left his mark on physiology, pathology, and morphology, in all of which he read and published papers embodying much independent and ingenious research. He was in his ninetieth year and leaves behind a reputation for industry, sagacity, and expository power but partially recognised in the many royal and civic honours conferred on him during his long and useful life.

Medico-Military Heroes.

If there is a subject that has yet escaped the all-utilising man of letters it might be found under the above title. I speak not now of such episodes in the army medical service as those of the Peninsular campaign, in which, according to General Sir George Napier, the English-speaking surgeons acquitted themselves with a courage only equalled by their professional skill. In Africa the service has a history exceptionally honourable—witness the heroism of Dr. James Ormiston McWilliam on the Niger, which so impressed Thackeray that in his "Lectures on the Humourists" he singles it out as an example of what is possible to British pluck. Even in the day now passing the humiliating reverses of Italy on Ethiopian soil have been redeemed by the splendid self-devotion of her medico-military staff—"the only, or almost the only, consolatory feature on the disastrous days of Amba Alagi and Abba Carima," said an Italian statesman to me lately. I gave some account in a recent letter of gallant young Alfredo Smuraglia of Orvieto who fell in the massacre of Mogadiscù in the Somali country. Since then details have come to hand which place the heroism of the "tenente-medico" in a specially significant light. Captain Cecchi's expedition, of which he was the professional adviser, had, after four hours' march, reached at 8 P.M. a giant forest, in the shadow of which the force, in the highest spirits, halted for the night. By 11 P.M. all were asleep; but about 3 A.M. a piercing cry aroused the slumberers—the Ascari sentinels had been assassinated by the Somalis. Then began a hand-to-hand encounter with the assailants in the dark which lasted till daybreak, when Captain Cecchi, without as yet the loss of a single European, began his retreat. At 7 A.M. the force got involved in an ambuscade and was at once the target for a shower of arrows. Captain Cecchi, ably seconded by Dr. Smuraglia, made a determined stand, and the whole party were doing deadly execution with their rifles and revolvers, till at last their ammunition gave out. "Il nostro dottore," says one of the three surviving eye-witnesses, "ferito da due freccie nella schiena se ne strappò con un coraggio inaudito" (our doctor, wounded by two arrows in the spine, wrenched them out with unprecedented pluck), and continued the struggle hand-to-hand till the force fought its way to a garden whence they were able to resume their retreat. But one by one the wounded fell out of the ranks by the wayside, and on each of the fallen—among them the doctor—the pursuing Somali pounced, dedicating them to Allah as they butchered them barbarously. The same evening from Mogadiscù sallied forth a company formed from the crews of the *Volturno* and the *Staffetta* to rescue the bodies; but, hard pressed by the Somali hordes, they brought back only an instalment, at the cost of two of their number wounded. It is not yet known whether Dr. Smuraglia's corpse has been recovered, but no effort will be wanting in the renewed endeavour to wrest from the Somalis the mortal remains of the young medical hero who, in the cause of science and professional duty, faced death as bravely as any combatant officer who "carries his life in his hands."

Dec. 27th, 1896.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Student Disorders in the University of Moscow.

SOME account of the student disturbances which about three weeks ago created some excitement in Moscow has been telegraphed to the English papers; but the explanation of those disorders, which has been very fully set forth in a document issued by the Government, has apparently not yet found its way to the English press. It is always difficult, if not impossible, for a foreigner to form a just judgement upon the questions involved in such entirely domestic affairs as these recurring conflicts between the students and the authorities. While the probability is that there is something to be said on both sides of the question the more desirable course seems to be to keep an open mind on the subject rather than express those crude and usually anti-Governmental opinions which too often disfigure foreign criticism of Russian affairs. At the same time it is well to record impartially the evidence on both sides. The document already referred to, which now lies before me, states with most unusual detail and apparently without *animus* the circumstances which led up to the recent disorders. It would appear that for many years past there has been a gradual growth in all Russian universities of student societies. These societies are generally known as *zemliatchestvos* (from *zemlia*, territory), as they usually consist of students coming from one and the same district. Thus there would be a Siberian, a Riazan, or an Ukraine *zemliatchestvo*. Originally formed on the principle of mutual aid societies, many of them have gradually altered their character, and admitting political agitators and revolutionists to their membership have become openly revolutionary. A few years ago most of the societies in the Moscow University united to form a "League Council of United *Zemliatchestvos*," consisting of forty-five societies and 1500 individuals. This council very soon showed that it intended to deal with matters quite outside the University by passing violent resolutions on all sorts of social and Imperial matters. At the time of the Toulon *fêtes* it sent messages to the French students of "disapproval of the servility of a free nation before the representatives of an autocratic *régime*," and it voted sympathy with, and sent money to, men on strike in different parts of the country. A number of other matters in which it interfered need not be mentioned here; suffice it to say that the authorities last year felt themselves bound to take action, and they interrupted one of the meetings and seized the papers. From these and other documents since seized it was clear that the "League Council" was practically a hotbed of sedition. The first article in a scheme of action drawn up only on Oct. 21st of this year runs thus: "The League Council declares that the chief end of the Union of *Zemliatchestvos* should be the preparation of 'fighting-men' in the political struggle." The council demanded the repeal of the present University Act (1884) and the re-enactment of the milder one of 1863; and it also tried to organise a general and simultaneous rising of students in all the Russian Universities. In this

Hosted by Google

it failed. However, on Nov. 18th (old style) it took advantage of the semi-anniversary of the terrible disaster at the popular fête at the time of the Coronation to organise a demonstration. Five hundred students marched out towards the cemetery where the "victims of a careless administration" lie buried, but they were prevented from reaching the cemetery by the police. The students returned to the University, and refusing to disperse were arrested in a body and taken to the large Manége opposite. All but 36 of the ringleaders were soon liberated. On the following day 400 students held a meeting and sent a deputation to the Rector of the University, who, however refused to meet them. On the next two days meetings were held and many arrests took place. In all, the police arrested 711 students. Of them 662 were tried by the ordinary University court, but the remainder, 49 in number, will be tried by the general law as more serious offenders. Those tried by the University court were divided into three groups; those of the first two groups were sentenced to be dismissed from the University, but with the right of admission to other universities at the beginning of the next academical year; those of the third group (461 in number) were also sentenced to dismissal, but with the right of re-entering the Moscow University next year. Students of the second and third group were further recommended to mercy, as they appear to have acted under compulsion; but not those of the first group (26 in number). These recommendations have been approved by the Ministry of Education, and on the 25th, 26th, and 27th of November (old style) the whole 636 students of the second and third groups were liberated with a reprimand. On Nov. 27th the Rector published a notice that students who in future should take part in similar disturbances would be at once sent down without appeal; but that students who do not wish to submit to the present University regulations might receive back their papers and be written in as "retired from the University at their own request." Thus has ended what threatened to be a somewhat serious domestic trouble, in which the authorities, so far as may be gathered, seem to have acted with most commendable moderation. Before closing this brief record it may be stated that the total number of students in the University of Moscow is about 3500, of whom a third belong to the medical faculty.

Postponement of the Jenner Celebration.

The Russian Jenner Commemoration, which was to have been held on Nov. 24th (Dec. 6th), but had to be postponed, is now fixed for the 15th (27th) of December.

Dec. 14th (26th), 1896.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Treatment of the Epileptic in Colonies.

THE progress of the colony for epileptics in the State of New York becomes more and more interesting. Although it has been opened for the reception of patients little more than a year, the results of this method of treating epileptics have been most pronounced. The annual report of the superintendent shows that nearly every case has gained in weight and in general health. In all cases the epileptic seizures have diminished in frequency to a marked degree, and in some instances this has been even extraordinary. The expression of the inmates has altered, so that, instead of the dull, hopeless look of the alms-house epileptics, one sees on all sides happy faces in which intelligence and hope are being re-awakened. The school has been successfully started for fifteen or twenty of both sexes. Much of the printing of the colony is now done by two or three epileptics in the colony's own printing office. Carpentry, sewing, painting, &c., are being carried on by the patients. They have their own epileptic blacksmith. The chief work of the inmates of both sexes is in the field and garden, and this labour also has a great effect upon the income of the colony. In regard to the effect of colony life upon epileptic seizures it may be noted that the first fifty patients who were under treatment five months and over before the close of the fiscal year had collectively 708 seizures. The same fifty cases, after five months treatment, had collectively, during the fifth month, 315 seizures. During the first month each case averaged fourteen attacks; during the fifth month, each case averaged six attacks.

An Ambulance Ship.

Surgeon-General Tryon of the United States Navy has proposed to add to our ships one or more suitably constructed vessels, the duty of which shall be to save and care for all wounded and drowning men during an engagement. It is recommended that this vessel shall be of such size as to render it easy of control in action and swift and efficient in rescuing the large number of sailors who are swept overboard in every naval conflict. Such a ship should receive the same courtesies accorded to the wearers of the Red Cross by all civilised nations. The advantages of such a plan have been so impressed upon the minds of all who entertain a proper regard for the lives of our brave sailors that the equipment and trial of these ambulance ships may be expected as one of the early improvements in the United States Navy.

Abuse of Dispensaries and Hospitals of New York.

The new President of the New York County Medical Society, Dr. Gray, in his inaugural address states that at the present time there are 26 hospitals and 114 dispensaries in this city. In the former, during the year 1895, 75,368 patients have been treated free and in the latter 661,803, making a total of 737,171, in a population of 1,851,060. In other words, the proportion of such free patients to the whole community is 39 per cent. There have been 92,529 free visits of patients to hospitals in 1895, and 1,387,170 free visits of patients to dispensaries. Out of 1,104,381 prescriptions that have been dispensed, there is no means of knowing exactly how many have been without charge, because 52 of the dispensaries have made no report to the State Board of Charities, while of the 62 that have been reported 16 make no charge for their medicines and 46 make nominal charges of from five to fifty cents, or nothing when the patient is unable to pay. Of these 114 dispensaries 60 take certain precautions to weed out the unworthy, such as making inquiries, questioning the patients, judging by their appearance and by the statements of physicians sending them, while the remaining 54 either make no inquiries or have made no report. Efforts were made to ascertain how many of the patients were non-residents, but the answers were usually very indefinite, one institution stating "Very few, if any," others "From 1 to 10 per cent.," while ten had treated 2124.

Carriers of Sick Passengers.

The Apellate Court of Indiana has decided that if a carrier accepts a passenger knowing that he is sick or infirm ordinary care must be used in seeing that he is transported safely and is given a reasonable time and proper assistance in getting on and off its cars. A carrier will not be required to accept or transport one having a contagious disease, or to accept as a passenger one who is physically disabled or unable to take care of himself. If a person desiring to become a passenger is unable, on account of extreme youth or old age or any mental or physical infirmities, to take care of himself he must be provided with an attendant to take care of him. The carrier is not bound to furnish him with an attendant.

Dec. 16th, 1896.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE MEETING OF FELLOWS.

AT the meeting of Fellows to be held on Thursday next, Jan. 7th, at 4 o'clock, Mr. Timothy Holmes has set down upon the agenda the following motion:—"That this meeting desires to call the attention of the Council to the published reports of the proceedings of the General Medical Council in the case of Mr. R. B. Anderson and to the remarks and action of Mr. Bryant on the occasion, and to ask the Council whether their representative has, in this instance, correctly construed their instructions."

Mr. Rivington will also move:—"That this meeting submits to the Council that no objection can apply to an advance from the funds of the College to prosecute Mr. Anderson's Appeal to the Privy Council, and therefore trusts that the Council will sanction a grant for that purpose."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Fellows of the College in the order of their seniority as Members of the College :—

Quick, William Henry (Surgeon-Major, I.M.S.), L.S.A. Lond.' Westminster and King's College Hospital; membership dated July 26th, 1880.
Harris, Herbert Elwin, M.B. Camb., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; Oct. 28th, 1885.
James, George Thomas, L.R.C.P. Lond., Westminster Hospital; Feb. 13th, 1890.
Jaffrey, Francis, L.R.C.P. Lond., St. George's Hospital; May 8th, 1890.
Nall, John Frederick, L.R.C.P. Lond., St. Bartholomew's Hospital; July 28th, 1890.
Riley, Frederick Ratcliffe, L.R.C.P. Lond., London Hospital; July 28th, 1890.
Elsworth, Richard Cogswell, M.B., C.M. Edin., Edinburgh University and Royal College of Surgeons of Edinburgh; July 30th, 1891.
Gladstone, Reginald John, M.D. Aberd., L.R.C.P. Lond., Aberdeen University and Middlesex Hospital; Aug. 1st, 1892.
Howat, Robert King, M.B. C.M. Glasg., L.R.C.P. Lond., Glasgow University and St. Mungo's College; Feb. 9th, 1893.
Castellote, Ramon Horace, M.D. Lond., L.R.C.P. Lond., University College Hospital; May 11th, 1893.
Davies, Hugh, M.B., B.S. Lond., L.R.C.P. Lond., University College and Guy's Hospital; July 27th, 1893.
Hall, Charles Beauchamp, L.R.C.P. Lond., St. Mary's Hospital; July 27th, 1893.
Scott, James Andrew Neptune, M.D., C.M. Glasg., L.R.C.P. Lond., Glasgow University and London Hospital; July 27th, 1893.
Pendred, Vaughan, M.B. Durh., L.R.C.P. Lond., Guy's Hospital and Durham University; Nov. 9th, 1893.
Ryall, Charles, L.R.C.P. Lond., L.R.C.P. Edin., Westminster and King's College Hospital; Feb. 8th, 1894.
Grace, John Johnston, M.B., B.S. Durh., L.R.C.P. Lond., Otago University, Dunedin and St. Bartholomew's Hospital; May 10th, 1894.
Pinch, Albert Edwin Hayward (Indian Medical Service), L.R.C.P. Lond., University College, and Royal United Hospitals and St. Bartholomew's Hospital; May 10th, 1894.
Hewer, Cecil Mackenzie, L.R.C.P. Lond., St. Bartholomew's Hospital; July 30th, 1894.
Every-Clayton, Leopold Ernest Valentine, M.B., B.S. Lond., L.R.C.P. Lond., Guy's Hospital; Feb. 7th, 1895.
Giles, Leonard Thomason, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; Feb. 7th, 1895.
Willis, William Morley, L.R.C.P. Lond., University College and General Hospital, Bristol, and St. Bartholomew's Hospital; May 9th, 1895.
Shaw, Harold Batty, M.B., B.S. Lond., L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds, and University College Hospital; July 29th, 1895.
Savage, Ernest Smallwood, M.B., B.Ch. Oxon., L.R.C.P. Lond., Oxford University and London Hospital; May 14th, 1896.
Bruce, Herbert Alexander, M.D. Toronto, L.R.C.P. Lond., Toronto University and General Hospital, and University College Hospital; Aug. 4th, 1896.
Melsome, William Stanley, M.D., B.C. Camb., Cambridge University and St. Thomas's Hospital; not previously a member.

Five other gentlemen passed the Examinations, but not having yet attained the legal age (twenty-five years) will receive their Diplomas at future meetings of the Council. Twenty-one gentlemen were referred for six months.

The following gentleman has previously passed the necessary examinations, and having now attained the legal age (twenty-five years) was also admitted a Fellow :—

Fraser, Forbes, L.R.C.P. Lond., St. Bartholomew's Hospital.

The following gentlemen having passed the necessary examinations, have been admitted Licentiates in Dental Surgery :—

Amphlett, Donald, Mason's College, Queen's and General Hospitals and Dental Hospital, Birmingham.
Anderson, Charles Frederick, University College, Royal Infirmary and Dental Hospital, Liverpool.
Anderson, Jonathan Harrison, University College, Royal Infirmary and Dental Hospital, Liverpool.
Carter, Charles Edward, Middlesex and the Dental Hospital of London.
Chatterton, Guy, Guy's Hospital, Dental Department and School.
Cribb, Harold Ernest, Charing Cross and the Dental Hospital of London.
Dalby, Charles Burkitt, Owen's College, Royal Infirmary and Victoria Dental Hospital, Manchester.
Donston, John Alexander Malin, Guy's Hospital, Dental Department and School.
Doyle, Clement Needham, Guy's Hospital, Dental Department and School.
Ellis, George Garnett, Guy's Hospital, Dental Department and School.
Evans, Sydney James, Guy's Hospital, Dental Department and School.
Goadby, Kenneth Weldon, Guy's Hospital, Dental Department and School.
Goodman, Thomas Dawson Edwin, Guy's Hospital, Dental Department and School.
Green, Walter, Charing Cross and the Dental Hospital of London.
Halliday, Alfred Reginald, Charing Cross and the National Dental Hospital.
Harding, George Herbert, University College, Royal Infirmary, and Dental Hospital, Liverpool.
Harrison, Arthur Edward, University College, Royal Infirmary, and Dental Hospital, Liverpool.
Hartnoll, Percy O'Bryen, Charing Cross and the Dental Hospital of London.
Hounsell, Ludlow Strangways, Guy's Hospital, Dental Department and School.
Humphrys, Jack Edmund, Charing Cross and the Dental Hos- of London.
James, John Joseph, University College, Royal Infirmary, and Dental Hospital, Liverpool.
Jeffery, Ernest, Middlesex Hospital and Dental Hospital of London.
Jones, William, Middlesex Hospital and the National Dental Hospital.
Knowles, Charles Heygate, Guy's Hospital, Dental Department and School.
Malone, Charles Albert, Charing-cross and the Dental Hospital of London.
Matthews, George Frederick Cole, Mason College, Queen's and General Hospital, and Dental Hospital, Birmingham.
Myers, Thomas Cyrill, Charing-cross and the Dental Hospital of London.
Naish, Godfrey, Guy's Hospital, Dental Department and School.
Parrot, Ernest Garner, Charing-cross and the Dental Hospital of London.
Pearse, Francis Henry, Middlesex and the National Dental Hospital.
Phillips, Charles Brooking, Middlesex and the National Dental Hospital.
Reece, Thomas Cadarn, Middlesex and the National Dental Hospital.
Ralph, Arthur Ernest, Middlesex and the National Dental Hospital.
Robertson, John Henry, Charing-cross and the Dental Hospital of London.
Simpson, Graham Scales, Guy's Hospital, Dental Department, and School.
Smith, Bernard, University College, Royal Infirmary and Dental Hospital, Liverpool.
Smith, Sidney, University College, Royal Infirmary and Dental Hospital, Liverpool.
Stephenson, John, Owens College, Royal Infirmary, and Victoria Dental Hospital, Manchester.
Turner, Henry Watson, Middlesex and the Dental Hospital of London,
Wale, Samuel Thomas, Middlesex and the Dental Hospital of London.
Wheeler, Ernest Alfred, Middlesex and the National Dental Hospital.
Whittington, William Borrett, Charing-cross and the Dental Hospital of London.
Young, Ralph Littlewood, Middlesex and the Dental Hospital of London.

Twenty-nine gentlemen were referred back to their professional studies for three months.

UNIVERSITY OF CAMBRIDGE.—At the examinations for medical and surgical degrees in the Michaelmas term, 1896, the following were successful in the subjects indicated :—

FIRST EXAMINATION.

Part I.—Chemistry and Physics.—H. Ackroyd, Gonville and Caius; J. F. Alexander, Trinity; Barton, Pembroke; Bennion, St. John's; Bottomley, Christ's; Butler, Emmanuel; Byles, King's; Clapham and Cohen, Emmanuel; Cole and W. H. Dickinson, B.A., Trinity; Dudley, H. Selwyn; Edwards, Downing; T. R. Elliott, Trinity; Frere, Pembroke; E. Gardner, Gonville and Caius; Goyder, St. John's; G. W. Greene, Downing; Hallstone, H. Selwyn; A. W. Harvey, St. John's; Haynes and Heath, Downing; Holtzmann, Christ's; E. G. Kelgren, Trinity; Kirk and Lanchester, King's; G. C. Lawson, Trinity; Leighton, St. John's; Leslie, Pembroke; Leveaux, St. John's; Lowe, Lucas, and Matheson, Gonville and Caius; Metthews, Downing; Molteno, Pembroke; Muspratt, Christ's; Nathan, B.A., and Noon, Trinity; Norman, L. Orton, and Paramore, St. John's; Paton, B.A., Gonville and Caius; H. Robinson, Trinity; Salzmann, Pembroke; Sapwell, B.A., Corpus Christi; Scarborough, St. John's; E. J. Scott, B.A., Trinity; A. V. Sedgwick, B.A., Gonville and Caius; Shone, Emmanuel; Snell, B. Spearman, and Spurrier, Gonville and Caius; Stiebel, Trinity Hall; Tonge, Emmanuel; Trigg, Christ's; Wakefield, Trinity; Wales, Sidney-Sussex; F. Whitaker and L. Wigram, Trinity; Wiltshire, St. John's; Woolley, King's; and Wylie, Pembroke.

SECOND EXAMINATION.

Part I.—Pharmaceutical Chemistry—Andrews, St. John's; Aveling, Christ's; L. E. H. R. Barker, Gonville and Caius; Bentley, St. John's; Bowdler, Sidney-Sussex; Bréhaut, B.A., H. Selwyn; H. S. D. Browne, Trinity; J. M Brydone, Jesus; Burrows, B.A., Emmanuel; E. M. Clark and H. H. Clarke, Trinity; A. J. Clarke, Emmanuel; Colyer, M.A., Catharine; Cooke, B.A., Sidney-Sussex; Deeping, Trinity; Elliston, Catharine; Emerson, Gonville and Caius; Eve, B.A., Emmanuel; W. M. Fletcher, B.A., Trinity; Franklin and Gayner, King's; Gilbart-Smith, B.A., Trinity; Greene, B.A., Corpus Christi; C. F. Hardie, Queen's; Heap, Sidney-Sussex; J. P. Hedley, King's; Hill, B.A., Emmanuel; Hodder and Hodgkin, King's; Holroyde, A. C. Hudson, and Ingram, Trinity; Kempthorne, St. John's; Kitchin, Downing; Laycock, St. John's; Le Lacheur, Trinity; Linnell, B.A., H. Selwyn; Naish, B.A., Emmanuel; Norton, Trinity; Nothwanger, St. John's; Parker, Pembroke; J. S. Pearson, Trinity; Perkins, St. John's; Phillpotts, Christ's; Rashleigh, B.A., and Reynolds, B.A., Trinity; Rob, St. John's; Roper, Gonville and

Hosted by Google

Caius; St. Clair Smith, Trinity Hall; Simey, B.A., King's; Skrimshire, Jesus; Smedley, Pembroke; Stockwell, King's; Taylor, Non-Collegiate; Thornton, Trinity; Wacher, St. John's; Wales, Downing; Walker, B.A., King's; Whale, Jesus; Wharton, St. John's; Wilgress, H. Selwyn; G. R. Wilson, Trinity; J. A. Wood, St. John's Wood, Downing; and Worthington, Gonville and Caius.

UNIVERSITY OF LONDON.—The following candidates were successful in the examinations indicated:—

M.D. EXAMINATION.

V. Every-Clayton, B.S., Guy's Hospital; Henry George Felkin, London Hospital; Samuel Ernest Gill and John Howell Griffiths, B.Sc., St. Bartholomew's Hospital; Ed. M. Hainworth, B.S., B.Sc., St. Thomas's Hospital; William Sampson Handley, B.S., Guy's Hospital; John Owen Harvey, St. Bartholomew's Hospital; Ralph Hopton, B.S., Yorkshire College; Gerald Stanley Hovenden, B.S., Guy's Hospital; Arthur William Kirkpatrick-Pickard, University College; William Edward Lee, St. Bartholomew's Hospital; Alfred Goodman Levy, William Britain Morton, and Frederic Layton Orr, University College; Leonard Arthur Parry, B.S., Guy's Hospital; Charles Herbert Perram, St. Bartholomew's Hospital; Frederick John Poynton, St. Mary's Hospital; Matthew Henry Raper, Middlesex Hospital; Ernest Noel Reichardt, St. Bartholomew's Hospital; A. John Rodocanachi, B.S., B.Sc., University College; Alfred Salter, B.S. (gold medal), Guy's Hospital; Edmond Wallace Selby, B.S., University College; William Shears, St. Bartholomew's Hospital; Ernest Jackson Smyth, B.S., B.Sc., University College; Robert Hunter Steen, St. Mary's Hospital; and George Harold Cawley Way, B.S., University College.

* Obtained the number of marks qualifying for the gold medal.

M.S. EXAMINATION.

Hamilton A. Ballance, M.D., University College; Harold Leslie Barnard, London Hospital; Julius St. Thomas Clarke, M.D., Guy's Hospital; George Hebb Cowen, London Hospital; John William Frank Jewell, M.D., Guy's Hospital; William Prior Purvis, M.D., B.Sc., St. Thomas's Hospital; Mary Ann D. Scharlieb, M.D., London School of Medicine for Women; and Thomas Morrell Thomas, Guy's Hospital.

B.S. EXAMINATION.

First Division.—John Howard Cook, University College; Edward Guy Dru Drury and James Henry Hugo, St. Bartholomew's Hospital; Arthur William Jenkins, University College; Hugh Mallinson Rigby, London Hospital; Herbert John Scharlieb, University College; and Ethel May Vaughan, London School of Medicine and Royal Free Hospital.

Second Division.—Wilfrid Allport, Queen's College and General Hospital, Birmingham; Emile Dupont Aubin, Middlesex Hospital; Cecil Banting and Charles Bolton, B.Sc., University College; William Francis Victor Bonney, Middlesex Hospital; Eustace Bernard Bostock, Mason College and General Hospital, Birmingham; Margaret M. Traill Christie, London School of Medicine and Royal Free Hospital; Walter Ernest Dixon, B.Sc., St. Thomas's Hospital; Archibald R. J. Douglas, St. Bartholomew's Hospital; George Gilbert Genge, St. Thomas's Hospital; Tom Harold Hunt, Yorkshire College; Charles Ernest Mackenzie Kelly, Owens College; Octavia Margaret Sophia Lewin, London School of Medicine and Royal Free Hospital; Carlton Oldfield, Yorkshire College; Norman Howard Pike, Guy's Hospital; George Basil Price, Bristol Medical School and St. Bartholomew's Hospital; Charles Roberts, Middlesex Hospital; Arthur Richard Harrie Skey, St. Bartholomew's Hospital; Arthur Herbert Spicer, Guy's Hospital; Arthur Stanley, M.D., St. Mary's Hospital; Frank Butler Thornton and Edward Owen Thurston, St. Thomas's Hospital; Francis Thomas Waldron, London Hospital; Lizzie Wilks, M.D., London School of Medicine for Women; and Francis Kenneth Wilson, Westminster Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. L. Mann has qualified as *privat docent* in Neurology.—*Kazan:* Dr. V. Rasumovski has been appointed Professor of Clinical Surgery in succession to Professor Kusmin, who has resigned.—*Rome:* Dr. Vittorio Ascoli has qualified as *privat docent* in Medical Pathology.—*Zürich:* Dr. W. Feliz, prosector in the Anatomical Institute, has been appointed Extraordinary Professor.

ST. LUKE'S HOSPITAL.—The Steward appeals for subscriptions on behalf of this institution. Last year the appeal funds, added to the amount voted by the committee of Governors, enabled a regular series of weekly entertainments to take place throughout the winter months, extending late into the year. The entertainments for the present season commenced in the first week of October, 1896, and have been carried on weekly up to the present time. The list will be kept open until the end of March, and the smallest amount will be gratefully appreciated.

THE COLONY OF EPILEPTICS.—On Saturday, the 19th ult., a handsome recreation hall, presented to the Colony of Epileptics at Chalfont St. Peters by Mrs. Cash, was formally opened by the donor. The hall is designed not only as a social meeting place for the colonists, but as a chapel wherein services can be held by the ministers of various denominations who visit the institution. After an entertainment, which included two solos on the violin by Miss Buzzard, Dr. Buzzard proposed a vote of thanks to Mrs. Cash, which was warmly received. The arrangements for the entertainment were in the hands of the honorary secretary of the colony, Miss Burdon Sanderson.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Committee of Management of Queen Charlotte's Lying-in Hospital, London, has received £100 from Messrs. C. J. Hambro and Sons, £100 guineas from Messrs. J. S. Morgan and Co., £1000 from the Dowager Lady Howard de Walden, and 100 guineas from Mr. P. Reid.—The treasurers of the Middlesex Hospital have received from "M. H. S." £100, £100 (annual subscription) from the Delwar Charitable Trust towards the maintenance of the Cancer Wards, and £100 from the executors of the late Sir A. A. D. Sassoon.—The committee of the Mary Wardell Convalescent Home for Scarlet Fever, Stanmore, has received £100 from Mrs. Allan.—The Board of Management of St. Mary's Hospital, London, has received under the will of the late Miss Ruth Watson £325 7*s.* 4*d.* and £1000 from Mrs. Arnold Gabriel to endow a bed in memory of her late husband.—The Board of Management of the East London Hospital for Children, Shadwell, has received from "G. S. B." £100 and £100 bequeathed by the late Mr. Joseph W. Prince of Croydon.—The Croydon General Hospital has received £100 bequeathed by the late Joseph W. Prince.—Mrs. George Holt of Sudeley, Mossley Hill, has sent a donation of £500 towards the funds of the Stanley Hospital, Liverpool, in memory of her late husband.—The Worshipful Company of Skinners has contributed £100 to King's College Hospital, London, being the fourth instalment of their promised donation of £500 in five years.—A donation of £105 has also been received from Mr. Charles P. Johnson.—The late Mr. Henry Wilson of Cottingham House, Yorkshire, has bequeathed 100 guineas to the Hull General Infirmary.—Mr. E. T. Hooley, of Risley Hall, Derby, has sent a donation of £1200 to the Derbyshire Infirmary.—The late Mr. Benjamin Goodman of Leeds has bequeathed £1000 to the Leeds Infirmary, £500 to the Leeds Public Dispensary, and £500 to the Women's and Children's Hospital.—Under the will of the late Mrs. Cuppage of Doddington, Whitchurch, the Whitchurch Cottage Hospital becomes entitled to a legacy of £200 free of legacy duty.—The treasurer of Charing-cross Hospital, London, has received a donation of £1000 from the Rev. Francis Jacox to endow a bed in the hospital.—The governors of the London Lock Hospital and Rescue Home have received £105 from the Worshipful Mercers' Company.—The Corporation of London has contributed 100 guineas to the Chelsea Hospital for Women and Convalescent Home at St. Leonards-on-Sea.—The late Miss D. Dixon of Broughton has bequeathed £1000 to the London Cancer Hospital, and £500 each to the Preston and County of Lancaster Royal Infirmary.—The Treasurer of the Montague Cottage Hospital has received £127 10*s.* under the will of the late Mr. Robert Elliner of Sevinton.—The Board of Management of the National Hospital for Consumption, Ventnor, Isle of Wight, has received a donation of 100 guineas from Mr. Chas. S. Burroughes.—The executors of the late Sir A. A. D. Sassoon have forwarded £100 to the Hospital for Sick Children, Great Ormond-street, Bloomsbury.—The treasurer of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen's-square, Bloomsbury, has received a donation of £100 from "E. M. E."—The Committee of Management of the North London Consumption Hospital, Hampstead Heath has received £350 from Mrs. Cash, to endow a bed in the hospital.—The late Mrs. Roxburgh of Bath has bequeathed £500 to the Bath Royal United Hospital and £100 to the Bath Ear and Eye Hospital.—By the death of Mrs. Memmoth, widow of Mr. George F. Memmoth, the following legacies become payable—namely, £250 each to the Bristol Royal Infirmary and the Bristol General Hospital, and £100 each to the Bristol Eye Hospital and the Hospital for Women and Children.—Mrs. Tubbs has contributed a donation of £100 to the New Hospital for Women, Euston-road, London.—

Ammonol
THE STIMULANT; IN LA GRIPPE.

CONSULTATION NOTES, NO. 3.

DEAR DOCTOR:—

More than a year ago we respectfully submitted to the physicians that we would be glad to consult with them concerning the use of AMMONOL STIMULANT IN DISEASE.

Of course we do not mean to say that we wish to usurp the place of a brother practitioner in such consultation.

Our intention is merely to present our views and claims from the manufacturer's standpoint, and as we have always received THE KINDEST CONSIDERATION FROM THE PROFESSION when stating our case, we feel confident now that you will listen patiently to us.

THIS IS THE SEASON OF LA GRIPPE.

From now until next summer this DISEASE or its SEQUELAE WILL RAVAGE THE COUNTRY.

Hosted by Google

The public press is loudly calling attention to the fact that the COAL FAMINE WILL LARGELY INCREASE DISEASE, AND WANT through the length and breadth of the United States during the next eight months.

May we not feel assured that beginning with LA GRIPPE we shall RUN THE WHOLE GAMUT OF CONCOMITANT DISEASES;—

PNEUMONIA, PHTHISIS, BRONCHITIS, LARYNGITIS, NEURALGIA, ETC.

In all these cases we can CONSCIENTIOUSLY URGE you, DOCTOR, as you value the welfare of your patients to make liberal use of

Ammonol

STIMULANT, ETHICAL.

THE ONLY STIMULATING ANTIPYRETIC AND ANALGESIC.

We take pleasure in enclosing for clinical test a sample of our 5 grain Ammonol Tablets.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the half-year ending Dec. 26th was given in last week's issue, which completed the second volume for the year 1896. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 will be ready shortly. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

"HOSPITAL REFORM."

MR. R. HILL SHAW, M.B. Dub., writes us a letter, for which we regret we cannot find room, on hospital reform. He observes: "We wage war not against charity but against the meanness of a large section of the public who 'sponge' on the kindly aid which is voluntarily and charitably contributed to help in sickness the deserving poor and needy man's misfortune, and who take an undue advantage of the want of unity and of greater independence throughout the medical profession in general, and in particular of the lack of a broad sympathy and of a wider unselfishness on the part of its members one towards another." Dr. Shaw has in these passages hit on the two parts of the explanation of the evils from which the profession is suffering. He will see that we have pointed this moral in our editorial columns.

W. J. L. G.—(1) A review of the book will appear shortly. (2) "Medical and Surgical Diseases of Children," by Ashby and Wright (Longmans), third edition, 1896, price 24*s.*

QUACKERY.

WE commented in THE LANCET of Dec. 19th upon the publications of the worst sort of quacks. The following letters are examples of another kind; they are not obscene or canting, but are nevertheless to be condemned. Letter No. 1 is from the patient to his proper physician. Letters 2, 3, and 4 are from the quack. The patient, we may add, had been treated at Brompton Hospital.

Letter No. 1.]

"DEAR SIR,—Pardon me for not having answered your kind note of October 13th before, but I have been very queer indeed since I have been here, otherwise I should have answered it before. I thank you very much for same and for your advice as to placing myself under a doctor here, but I am sorry to say they are very expensive here and I cannot afford the money as I have a young family. I am at present taking Owbridge's Lung Tonic, although it does not seem to benefit me much. I have taken two bottles.

"I answered an advertisement in the newspaper (enclosed) and the circulars I enclose are the result. I shall esteem it a very great kindness if you will give me your advice as to whether you think it would be any use placing myself under the treatment, as you know exactly how my health is and if it is likely to be of any standing benefit to me. The reason I trouble you is because I am not in a position to throw £2 2*s.* away if it would not do me any good, and thinking you may know something about this cure I venture to ask your advice on same.

"Thanking you, Sir, for an early reply and apologising for troubling you, "I am, Sirs, yours obediently,

"—— ——."

Letter No. 2.]

"Specialist Pulmonary Institute Dir. Paul Weidhaas, Proprietor of the Institute for the Cure of Asthma and Pulmonary Diseases, Nieder Wessnitz, near Dresden, Germany.

"Oct. 29, 1896.

"Your inquiry concerning my treatment to for asthma to hand I thank you for your confidence and will try to justify it every respect. The instigation to introduce my cure in proceeded from Professor Dr. Sawyer in Brighton, whose son I cured from a long standing suffering of asthma, after change of climate and all other cures had been unsuccessful and the disease threatened to develop into consumption. I have used my cure in thousands of difficult cases with complete and lasting success, not merely ephemeral. It can be followed without interference of the daily occupations and at home; and consists besides prescriptions of a physiatric nature in the employment of an instrument for atomisatrie, by the use of which the vessels of the lungs charged with blood are contracted and emptied; and further of a specially composed tea of special and excellent general effect. The results are as already mentioned lasting for I do not only try to conquer the particular symptoms of the disease as is usually the case in other treatments but I strive to remove the causes this is proved by my wonderful results which I have attained by patients who had been given up as incurable. The total fees including instrument, information and the direction of the cure amount to 2 guineas, no matter whether you claim my advice for only a short or a longer time. One half of the fee is due at the beginning the other half at the completion of the cure. The only other expenses are at the beginning of the cure 3*d.* per day for the tea. "Yours faithfully

"Specialist

"Pulmonary Institute

"Dir. PAUL WEIDHAAS."

Letter No. 3.]

"DEAR SIR,—Enclosed I send you a list of questions which you will please fill out, the answers of which will determine more securely the position of the diagnosis and the fixing of the necessary correct directions, than a personal physical examination, by which very frequently all sorts of errors occur.

"After receipt of the list thus filled out, and half the cure-fees, I will send you at once all you require for the cure, and would ask you to report to me progress of recovery, so as to enable me to make the analogous further arrangements. "Yours truly,

"PAUL WEIDHAAS."

Letter No. 4.] "Nov. 7.

"DEAR SIR,—Though your sufferings are as you know your self, not to be called slight it is to be recommended to make a last trial I can tell you to your satisfaction that I have cured many who were at death's door. In consideration of your present position I am willing to meet you as to the fees, what do you say to ½ a guinea for the first instalment? For the rest I would give you time to pay when it suits you as my chief aim is to effect a cure. If you agree to these terms I will send you everything you require for the cure.

"Yours faithfully,

"PAUL WEIDERHAAS."

Letter No. 3 is particularly interesting as an example of illogical reasoning.

H. E. T.—No standard work has come under our notice upon this extremely limited subject. We recommend our correspondent to consult two or three standard works of anatomy and physiology and some good manual of dental surgery and mechanics.

RECOVERY OF MEDICAL CHARGES.

AT Clerkenwell County Court a few days ago Mr. Charles Jeffrey Morgan, L.R.C.P. and L.M. Edin., M.R.C.S. Eng., 546, Caledonian-road, sued Mr. Charles R. Townley, clerk, of 9, Richmond-place, Russell-road, Holloway, for £13 4s. for professional attendance and medicines in the autumn of 1895. The patients attended were three children of the defendant suffering from diphtheria, two of whom died, the defendant's wife, who also suffered from that disease, and himself for sore-throat. The services included a tracheotomy and the administration of antitoxin. The charge was at the rate of 2s. 6d. a visit with medicine. When the account was sent in a reduction was asked for and the plaintiff agreed to take off £1, whereupon the defendant brought a charge of negligence and the plaintiff naturally refused to make any reduction. This charge was reiterated in court, but withdrawn by Mr. Randall Moore, the defendant's solicitor. The jury found for the plaintiff for £7 10s. over and above £1 10s. paid into court by defendant. We regret this reduction of charge, but the defendant will get little satisfaction from the rider of the jury or the just remarks of the judge. The jury expressed regret that a charge of incompetency had been brought against the plaintiff, and the judge said he "had a strong opinion about the case. He had some experience of illness in the household and knew how much doctors were in the habit of doing for their patients and how little they charged." The reduction in the bill by the jury was clearly due to the appeal *ad misericordiam* of the defendant, who said he had only £2 10s. a week.

"DISINFECTION OF BOOKS AFTER SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—In reply to "A. B. S." books must be disinfected by hot (moist) air; steam will entirely destroy the leather binding and sulphuring is not reliable. I would advise "A. B. S." to get the disinfection done by some skilled person—such as Mr. W. C. Lacy, Town Mead Wharf, Wandsworth Bridge, Fulham, S.W.—and damage will be less likely to occur.

I am, Sirs, yours truly,

Dec. 23rd, 1896. J. GAY.

IN RE "DR. WILLIAM BEDELL BENISON, DECEASED."

THE *Birmingham Daily Mail* has an advertisement in regard to the course to be taken by persons having claims on the estate of the above gentleman, deceased, in which is curiously and prominently announced the fact that "Dr. Harris, L.R.C.P., &c., &c., who attended the late Dr. Benison in his illness and has since conducted his practice, will continue Dr. Benison's practice at Valentine-road, King's Heath, for the present." Such an announcement would have been better made by circular to individual patients and with strict adherence to proper titles.

X. Y. Z.—One tabloid night and morning is not an excessive dose. It is too early in the history of the preparation to speak with any certainty from a clinical standpoint; but we publish an analytical note upon it this week.

INSANITY AND TUBERCULOSIS AMONG NEGROES.

"PREVIOUSLY to the abolition of slavery," writes a correspondent, "there was very little tuberculosis or insanity in America amongst the negroes of the Southern States, who were observed to enjoy a remarkable immunity from both affections. After emancipation they appeared to quickly lose this immunity, and at the present time are exceedingly susceptible to both. Formerly, although in a state of slavery, they are said to have been well cared for, compelled to lead orderly, regular lives, and kept from dissipation and excess. Freedom removed these restraints, and they quickly plunged into riotous and vicious habits. A physician who has investigated the subject writes in a transatlantic contemporary that "the rapid increase of insanity and consumption in this race is due to a combination of causes and conditions. They have developed a highly insane, consumptive, syphilitic, and alcoholic constitution which predisposes them to diseases they were formerly free from. In this disturbed and unstable condition they seem to be totally unable to resist the slightest excitement. Recent mortality returns show that the death-rate of the coloured people from tuberculosis is three times as high as that of the whites."

R. N.—Mr. ——, Fleet-Surgeon, R.N., appears to us to be the preferable style.

"SERIOUS CHARGE AGAINST A MEDICAL MAN."

WE have before now had to protest against the misuse of this title in connexion with paragraphs in the lay press. It is constantly employed when the person charged has no legal claim whatever to the position of a "medical man." In the case of the individual arrested at Devonport just before Christmas we have been unable to find the name of Edwin Alfred Cormack upon the Medical Register, while we cannot ascertain that anyone of this name has been removed from the official list.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

TUESDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (6th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2 30 P.M.).

SATURDAY (9th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

TUESDAY (5th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Papers:—Dr. A. A. Kanthack and Mr. T. W. Connell: Some Points in the Morphology of the Tetanus Bacillus.—Dr. D. Drew: Villous Papilloma of the Kidney, Ureter, and Bladder.—Mr. J. R. Lunn: (1) Excision of Knee Joint; (2) Femur which had been Trephined; (3) Duct Carcinoma (?) in a Man aged ninety-one years. Card Specimens: Dr. Parkes Weber: Cardiac Thrombosis.—Dr. Th. Fisher: Broncho-pneumonia with Dilated Tube in Child aged five years.

WEDNESDAY (6th).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. C. H. Roberts, Dr. A. Routh and others. Dr. Macnaughton Jones: Note on a Case of Eclampsia. Papers:—Dr. W. S. A. Griffiths and Dr. A. W. W. Lea: On Breech Presentation with Extended Legs.—Dr. Giles: The Cyclical, or Wave, Theory of Menstruation, with observations on the Variations in Pulse and Temperature in relation to Menstruation.

FRIDAY (8th).—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. R. Brudenell Carter: Case of Gunshot Wound of the Eye.—Dr. W. P. Herringham: A Case of Paroxysmal Tachycardia in a Girl aged thirteen years.—Mr. C. S. Wallace: A Case of Fracture of the Axis.—Mr. J. E Lane: Two Cases of Gastro-enterostomy illustrating the use of Murphy's Button.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FRIDAY (8th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury). — 3 30 P.M. Dr. James Taylor: Electrical Testing and Treatment.

During the week marked copies of the following newspapers have been received:—*Worcester Herald, Hull Times, Daily Mail, Bolton Chronicle, Manchester Guardian, Rocket, Glasgow Evening News, Leicester Post, Dundee Advertiser, Admiralty and Horse Guards Gazette, Birmingham Argus, Sheffield Telegraph, South Wales Daily News, Times of India, Pioneer Mail, Newbury Weekly News, Hereford Times, Leeds Mercury, Forfar Herald, Midland Free Press, Eastbourne Chronicle, Gravesend Standard, Sussex Daily News, Bucks Herald, Liverpool Daily Post, Gray's Standard, Colchester Gazette, Northampton Mercury, Portsmouth Times, Yorkshire Post, Halifax Courier, Whitehall Review, Liverpool Courier, Oldham Standard, Lincoln Gazette, Sheffield Independent, Keene's Bath Journal, Somerset County Herald, Essex Telegraph, Architect, Bristol Mercury, Chatham News, Builder, Scotsman, Grocers' Journal, Newcastle Journal, South Eastern Gazette, East Anglian Weekly Times, Royal Cornwall Gazette, Grimsby Observer, Folkestone Express, Launceston Weekly News, Wakefield Express, Surrey Comet, Reading Mercury, Birmingham Daily Post, Sanitary Record, West Middlesex Herald, Surrey Advertiser, Mining Journal, Brighton Gazette, Local Government Journal, City Press, Hertfordshire Mercury, Le Courrier de la Presse, Local Government Chronicle, The Australasian Medical Gazette, Evening Express, Liverpool Daily Telegraph, The Stock Exchange, Educational Times, Luton Reporter, &c., &c.*

Hosted by Google

Communications, Letters, &c., have been received from—

A.—Dr. F. S. Amley, Halifax; A. B., Lond.; Antikamnia Chemical Co., St. Louis, U.S.A.; Mr. C. M. Anderson, Christchurch, N.Z.; Messrs. R. Anderson and Co., Lond.; Dr. W. C. Alexander, Wellington, N.Z.

B.—Mr. J. H. Busteed, Romford; Mr. P. S. Bridgeford, Lond.; Dr. C. Bodon, Budapest; Messrs. F. B. Benger and Co., Manchester; T. B. Browne, Ltd., Lond.; Mr. C. Birchall, Liverpool; *British and Colonial Druggist*, Lond.; Mr. L. Browne, Lond.; Dr. S. A. Bontor, Great Berkhamstead; B. R. A., Cape Town, South Africa; Dr. I. Banks, Aberdare; Messrs. Burgoyne, Burbidges, and Co., Lond.; Mr. R. Baker, Lond.; Messrs. Burroughs, Wellcome, and Co., Lond.; Dr. J. Blyth, Attercliffe Common; Dr. Lauder Brunton, Fleet.

C.—Dr. E. Carmichael, Edin.; Messrs. J. A. Carveth and Co., Toronto; Messrs. J. W. Cooke and Co., Lond.; Messrs. T. Christy and Co., Lond.; Messrs A. H. Cox and Co., Brighton; Calcutta Medical School, Asst. Sec. of; City of London Hosp. for Diseases of the Chest, Sec. of; County Borough of Oldham, Med. Off. of Health of; Cortland Wagon Co., Lond.; Central London Throat and Ear Hosp., Sec. of; Cornwall County Asylum, Bodmin, Med. Supt. of.

D.—Dr. A. Duke, Broadwater; Messrs. Duncan, Flockhart, and Co., Edin.; Messrs. Down Bros., Lond.; Messrs. A. Durant and Co., Lond.; Department of Health, City of Chicago, Commissioner of; Dr. H. J. Davis, Lond.; Messrs. Davies and Co., Lond.; Messrs. S. Deacon and Co., Lond.

E.—Messrs. Evans, Sons, and Co., Liverpool; Messrs. Evans, Gadd, and Co., Exeter.

F.—Mr. R. Favell, Sheffield.

G.—German Hosp., Lond., Supt. of; Dr. J. Griffiths, Cambridge; Messrs. D and W. Gibbs, Lond.; Dr. A. Gamgee, Montreux.

H.—Mr. T. Holland, Lond.; Messrs. C. J. Hewlett and Son, Lond.; Home Trading Co. (The), Lond.; Surg.-Maj. E. Hopkins, Army Medical Department; Hosp. for Consumption, Lond., Sec. of; Hosp. for Women, Soho-square, Dean of; Mr. Geoffrey Hungerford, Lond.; Mr. J. Heywood, Manchester; Mr. J. C. Humphreys, Tunbridge Wells; Mr. P. Hayes, Bury; Mr. W. C. Hughes, Lond.

J.—Dr. F. Jordan, Birmingham; Messrs. W. and A. K. Johnston, Edin.; Johns Hopkins University, Baltimore, Librarian of; Dr. O. Jennings, Paris; Johannis, Ltd., Lond., Asst. Manager of.

K.—King's College Hosp., Lond.; Mr. D. S. Kemp, Lond.; Messrs. Kilner Bros., Lond.

L.—Dr. Patrick Letters, Valentia Island, co. Kerry, Ireland; Locum Tenens, Leicester; J. F. Lehmann's Verlag, München; Liq. Carnis Co., Aston Clinton; Mr. J. W. Lewis, Brynamman; London Temperance Hosp., Sec. of.

Scientific Methods and Products.

THE VEREKER AMMONIUM CHLORIDE INHALER.

INHALATION is undoubtedly the best method of applying certain drugs directly to the larynx, trachea, bronchi, and lungs, and the inhalation of Ammonium Chloride especially is regarded by leading authorities as of great value in naso-pharyngeal and laryngeal catarrh and œdema, and in chronic and senile bronchitis. Various inhalers have been made, but in many, if not all, of these, absolute neutrality of the fumes is not secured. This is a point of much importance, which, if neglected, will cause grave disappointment with an otherwise useful and satisfactory method of treatment. When the fumes are either acid or alkaline they are extremely irritating and frequently aggravate rather than alleviate the symptoms.

Besides possessing other advantages, the Vereker Ammonium Chloride Inhaler is so constructed that neutrality is secured by the simple expedient of lowering or raising one of two little tubes. Simplicity with effectiveness are characteristic features of these inhalers. The acid and ammonia are contained in glass bottles, and the ammonium chloride itself passes through water contained in a similar receptacle. The result is that the fumes are more abundant and denser than is the case when sponges, pumice stone, or other absorbent media are used instead of bottles. The vapour may be further medicated if desired by dropping a crushed vaporole or a few drops of a volatile inhalant into the wash bottle.

Vereker Inhalers are supplied to the medical profession at 5/- each.

THE PINOL-EUCALYPTIA DRY INHALER (B. W. & CO.).

Dry inhalations of eucalyptia, pinol, or pure terebene are serviceable in phthisis to allay irritation and cough, and in catarrhal conditions of the nose and throat. The simplest and most perfect method of employing these agents is by means of the B. W. & Co. Pinol-Eucalyptia Dry Inhaler

The medicament is dropped into the wide end of the glass tube until the absorbent is sufficiently charged. By inspiring through the mouthpiece the air passes through the charge and becomes laden with the medicament.

The Pinol-Eucalyptia Dry Inhaler can be carried and used without fear of breakage during the usual routine of business, and is now generally used in the palliative treatment of throat and chest affections. It is issued in neat cases with a supply of Pinol and Eucalyptia at 1/2 each.

SAXIN "TABLOIDS."

Saxin has been aptly termed "the sweetest thing on earth," being about 600 times sweeter than sugar, and double the sweetness of Saccharin. It is perfectly harmless as it undergoes no change in its passage through the digestive system, but simply imparts its delicate sweet flavour to the food or fluid with which it is used. For these reasons it is indicated in such conditions of disease as diabetes mellitus, gout, obesity, glycosuria, &c, in which the patient is debarred from taking sugar and yet retains an intense desire for the sweet flavour to which the palate has, by long use, become accustomed.

Saxin has important qualities which render it superior to other sweetening substances. It is unfermentable and permanent. It operates antiseptically and prevents decomposition. In flavour it is more delicate than any other sweetening agent, including saccharin, and in the shape of "Saxin Tabloids," ¼ gr. each, it provides the maximum amount of sweetening power in the smallest possible space.

A small bottle, containing 100 or 200 "Tabloids," can be carried in the vest pocket without the slightest inconvenience, and thus the patient, who must avoid sugar, can have a delicately flavoured, harmless sweetening agent always handy when at business, or when travelling at home or abroad.

Saxin "Tabloids," ¼ gr., are each equivalent to one lump of best loaf sugar and are supplied in bottles of 100 and 200 "Tabloids" at 7d. and 1s. 1d.

EMOL-KELEET.

Since the favourable reports which marked the introduction of this preparation many appreciative opinions have been expressed both by physicians and by the professional press.

THE LANCET says:—On account of its remarkable velvety smoothness it should possess a unique value as a dusting powder in the treatment of cutaneous diseases, &c., and for allaying irritation. We have not examined a more unctuous earth."

BRAITHWAITE'S RETROSPECT OF MEDICINE says:—"Emol-Keleet is the most beautiful, impalpable, mineral powder with which we are acquainted, and promises to supersede all the older forms of dusting powders. We have made use of it for some time past in the treatment of eczema, especially in infants and young children, where dry and soothing agents are most desired, and have found it to be a most excellent application in such cases, while the readiness with which it can be used and its absolute freedom from all risks of decomposition, add largely to its value.

Emol-Keleet is supplied to the profession in boxes at 9d. each.

BURROUGHS, WELLCOME & Co.

Kepler Solution

of Cod-Liver Oil in Malt Extract

Contains the oil in molecular association with Kepler Malt Extract, and so ensures its complete absorption. The benefit to be derived from cod-liver oil depends entirely on the proportion absorbed, and this accounts for the failures recorded where raw oil is administered. In the case of Kepler Solution the taste of the oil is so disguised that it can be taken by the most fastidious patients without nausea or other unpleasant effect. It is the most palatable and easily digested of any form of oil. Children take it readily. Supplied in two sizes at 1s. 8d. and 3s. per bottle.

A Lecture
ON
THE SPREAD OF PLAGUE.

Delivered before the Epidemiological Society on Dec. 18th, 1896,

BY JAMES CANTLIE, M.B. ABERD.,
F.R.C.S. ENG.,
LECTURER ON APPLIED ANATOMY, CHARING CROSS HOSPITAL MEDICAL SCHOOL; LATE OF HONG-KONG.

(*Concluded from page 7.*)

WHAT has been termed the "miasmatic" method of infection bears distinctly upon the maintenance and epidemicity of plague. Miasmatic infection implies a soil-bred disease—a disease existing, as we assume malaria does, in the earth itself, in the water, or in some particular form of fermenting or decomposing material in which the germ finds a nidus. In a neighbourhood so infected the disease is endemic, as manifested by the fact that again and again the disease recurs—that after a few months of seemingly complete disappearance the disease crops up and runs a more or less severe course. The time of its disappearance may be merely one of hibernation, or the climatic conditions may be unsuited to the activity or the evolution of the bacillus of the disease; but when a sufficiency of time elapses or the requisite quantity of heat, moisture, and whatever else is necessary to the growth of the bacilli are attainable the revival of its infective power is speedily manifested. Whilst comparing malaria and plague as miasmatic disease it is not to be inferred that there is any bearing in the relation of the one to the other. In fact, Dr. Mouchard, writing from Yunnan, cites the cases of Mentz, a town on the hills, and Manhao, a town on the river 3600 feet lower. In the former plague is endemic, but in Manhao malaria is so great a scourge that the Mentz muleteers refuse to spend the nights in the town.

Infection of, and by, animals.—In support of plague being a soil-bred—a miasmatic—disease is the fact, so often announced, that rats are invariably affected. From Canton, Hong-Kong, Macao, Pakhoi, Yunnan, from hills in the north-west provinces of India, and, most recently of all, from Bombay the observation is constant, definite, and most pointed. The first time particular notice is taken of the death of rats in connexion with plague is in Mr. Rocher's report on the Yunnan plague, some twenty years ago. The Chinese firmly believe the poison emanates from the soil; so far is their conviction carried that they estimate with mathematical precision its gradual rise above the ground. The graduation is estimated by the successive animals that are attacked. The sequence is affected apparently by the height of the animal's breathing apparatus from the ground, the small animals being the first seized and the larger or more elevated animals the last to be attacked. Rats, poultry, pigs, dogs, goats, sheep, cows, buffaloes and last of all man as being the tallest of these is their scale of infection. This is not to be taken seriously but the infection of some of these animals is undoubted.

Rats.—On all hands rats are reputed to behave peculiarly and with a wonderful constancy. Before, or it may be during, an epidemic of plague, or before the individuals in any particular house in an infected locality are stricken, the rats leave their haunts and seek the interior of the house. They seem careless of the presence of man and run about in a dazed way with a peculiar limping jerk or spasm of their hind legs. They are frequently found on the bedroom floor, or on the tables, but not unfrequently their death is known by the putrefactive odour of their decomposition arising from beneath the flooring. So pertinent has this rat affection become, that during the epidemic in Macao in 1895, the Chinese and Portuguese left their houses when the diseased rats invaded their premises. The cause of the rats' behaviour is undoubtedly disease, and the symptoms tally wonderfully with plague symptoms of man. Dr. Rennie examined them carefully in Canton and noted the following post-mortem appearances: (1) the stomach was distended and filled with particles of food, sand, and indigestible substances, and the mucous membrane was red and inflamed towards the pyloric end; (2) the liver was much enlarged and congested and contained ova of tænia and distoma: (3) there was congestion at the base of the lung present in about 40 per cent.; and (4) glandular enlargement was present in 30 per cent. of those examined. There is no doubt now that the disease in the rat and man are identical. The bacillus of plague has been met with in every case of rat disease of this description where it has been searched for. The infection of the rat is raised from being a mere popular belief into one of scientific precision, and we must now accept the rat at any rate as one animal liable to plague. Whether the rat is affected previously to, coincidently with, or subsequently to, man being attacked is open to question. Is the disease amongst rats a forerunner of its outbreak in man, and, if so, are they a means of infection? These are, of course, two separate questions.

Surgeon-Major S. J. Thomson, Deputy Sanitary Commissioner, North West Provinces, India, who made excellent reports on the outbreaks in Ghurwal and Kumaon in 1886 and again in 1888, writes as follows[1]: "A fact mentioned in the Hong-Kong epidemic by Dr. Cantlie is the great mortality amongst rats. This is also most marked in the case of outbreaks of *matra-mari*, a hill plague; but I should add that it is generally observed *before* the appearance of the disease amongst human beings. So well is this recognised by the people that they will sometimes vacate their villages for fear of an outbreak of matra-mari when once this rat mortality has become distinctly noticeable." In Canton, Dr. Rennie writes that "from districts of the city where the diseases had lasted for some time rats entirely disappeared; but in other parts to which plague subsequently extended the rat mortality was most marked. So convinced were the Chinese of the power of the rat to infect that certain officials took steps to have all the dead rats collected, and at one gate as many as 22,000 rats were collected by May 8th, which, taking into consideration the date of the outbreak, must imply that the collection was made in a few weeks. The *Times of India*, Sept. 30th, 1896, contains the following:—"It was known *more than a month ago* to all the people of Mandvi (the district in Bombay where plague first broke out in September, 1896) and to all the municipal sweepers in the district that the rats were dying in thousands all over the districts. They were found dead and dying almost everywhere and in places where dead rats were never found before. The children amused themselves every morning by throwing them from the staircases into the streets and gulleys. The great rat mortality only became known recently and yet what a volume of information was it capable of conveying if it was only rightly used. It is universal history that rat and plague mortality go together; the merest tyro in hygiene knows the fact," &c.

The rat therefore seems to be infected before the human being; and the fact of dead rats being found about the house during the plague epidemic is a true warning that the inmates of the house will in all probability be affected. How is the rat infected? 1. Experiment proves (*a*) that the rat is inoculable and dies from a disease identical with bubonic plague in man; the inoculation of both the blood and inflammatory fluids of the plague-infected is effective; and further, a pure cultivation injected hypodermically also sets up signs and symptoms of rat plague and causes death within a few days; and (*b*) that supplying the animal with plague-infected food, whether flesh or cultivated germs, causes plague in rats. How does the rat in his natural state become infected; by inoculation? We cannot assume that every rat has a scratch or open wound by which it is infected. It is more likely he inhales or inbibes the poison either as a miasm in concentrated form or he ingests it with his food. It may be both forms of infection are at work; and, further, it must not be forgotten that rats are cannibal in their habits, and direct contagion must play a large part, if not the major part, in the general infection of their tribe. That it is some general infection and not a chance inoculation is manifested by their sudden and simultaneous seizure—a seizure so sudden that scores of dead and diseased rats will be found in a single house of any size within a few hours. An interesting observation in connexion with the Calcutta affection is "that although Calcutta was believed to be the seat of plague and the plague bacillus was pronounced to have been proved in six cases no rats died." This was

[1] Brit. Med. Jour., Sept. 8th, 1894.

Hosted by Google

regarded as a peculiar and, shall I say, an unprecedented condition, but the explanation is simple enough. The rats did not die, as true plague did not exist in Calcutta, the cases of fever with bubonic swellings being found to be minus a toxic bacillus. This is in accordance with all previous experience. The Calcutta form of disease is benign and no record of rats dying during its prevalence has ever been made. Are we to doubt our belief in the diagnostic value of the bacillus or admit a new disease into our category—a benign polyadenitis? It may be we are called upon to do neither, for we have evidence to show that non-virulent forms of the bacillus can be cultivated and that a bacillus can be found in the soil and cultivated which behaves like the non-virulent bacillus extracted from true plague cultures. These points will be discussed later. 2. An observation by Dr. Thomson in the North-West Provinces of India is worth recording. "In these hill tracts the huts are usually double storeyed, the upper storey being occupied by human beings, and the lower by cattle, goats, &c. It is the custom of the villagers to store the grain in pits under the floors of the huts, and the soil is very foul from the excrement of animals &c. The theory among the people is that the rats eat the grain which is often musty. Most of these hill people are very poor and would consume such grain, which is their principal food, even when musty and clearly affected with fungoid disease." It is some widespread source of infection by which the rat is infected. Dr. Rennie tells us that the places from which the exodus takes place are left without a rat to be seen.

If not from grain or from inoculation, whence comes the poison. From the soil? Dr. Rennie found sand and indigestible material in the contents of the dead rats' stomachs. May this sand have been the source of infection? I kept guinea-pigs on soil from the grave of a plague patient who had been dead for two months; the guinea-pigs were not infected, but perhaps the earth had hardly had time to become infected. If the poison is miasmatic and emanates from the soil as a gas or cloud the rat in his close stifling quarters is exposed to a concentrated inhalation. I have already mentioned the soldiers employed in digging out the filth from plague dwellings being seized and the infection was presumed to be brought about by the intensity of the virus. Therefore, we cannot presume that the rat can be infected by a miasm merely. Of the three forms of infection discussed we may safely lay aside inoculation. We may hesitate over the infection by fungoid grain, but although the musty grain would render the disease endemic it could not account for an epidemic spreading to districts where the grain is sound, unless we assume the rat is the carrier. We are left, therefore, either with actual consumption of poisoned material or the concentrated emanation from an infected soil as the means of introduction into the rat's economy.

Snakes.—Dr. Thomson remarks[2]: "Moreover, when rats are thus dying dead snakes also are said to be found about the site in unusual numbers" Later he remarks: "The snakes eat the rats." From the North-Western Provinces of India we also have record of snakes being affected during plague outbreaks. The snake is not observed as one of the animals affected in the list given by the Chinese, but the infection is natural and the infection through their consumption of the rat is feasible. The possibility, however, of direct miasmatic infection must not be lost sight of.

Dogs.—In the *Chinese Customs Medical Gazette* in the forty-seventh and forty-eighth issues we read that dogs died during an epidemic of plague. The observer ascribes it to the dogs eating the flesh of human beings or any other animal dead from plague. In the same paper it is described that in Yunnan the dying are removed out of the houses to repose in the streets in accordance with Chinese customs, and that those dead and dying from plague are found outside the dwellings or even outside the town walls. He has, moreover, seen the dogs eating the flesh of those dead from plague. In Hong-Kong we had no special mortality amongst dogs, nor have Canton or Macao anything to say on the subject, but the dead were better cared for than in Yunnan and no dog could get at them. It would seem as though the dog were infected by eating the flesh. In the places mentioned such an opportunity was not afforded him, but in the town of Mentz, Yunnan, the custom as to the disposal of the dying seems to explain the infection of the dog.

[2] Brit. Med. Jour., Sept. 8th, 1895, p. 560.

Pigs.—It is even more important to ascertain whether or no the pig is infected. Pork is largely consumed by Chinese; and, moreover, Europeans in the East seldom or never eat Chinese-fed pork. The Chinese died from plague, whilst the Europeans enjoyed an immunity from the disease; nothing seems more conclusive than that pork was the infecting food. Moreover, most of the pork brought to the Hong-Kong market comes from Pakhoi, a town where plague has been endemic for years. The first point to be settled is—Does the pig suffer? Not as a rule. The pigs from Pakhoi showed no falling off in numbers, and they were not sickly; the former condition would have obtained had plague thinned their numbers in Pakhoi, and the latter would have been found out when they reached Hong-Kong, where careful inspection of all food supplies is made. Dr. Mouchaud writes that the pigs died in Yunnan, and he states that "we saw on some roads dogs and pigs feeding undisturbed on corpses which no one cared to bury. These animals fell victims to their greed and succumbed to the scourge." Further, plague has been produced in the pig experimentally, all of which goes to prove that pigs die from plague after consumption of corpses dead from plague and inoculation; but that pigs are not primarily liable to plague in the same way as rats and pigeons seems conclusively shown.

Oxen, sheep, and *goats* are not known to be subject to a disease allied to plague, nor are they affected by any fatal malady during the time plague is epidemic. As regards sheep, Custaldi states that plague in Kurdistan was preceded by a fatal epizootic among sheep; that they had plague, however, is not stated.

Jackals are known to be subject to the disease in Yunnan. They are more prone than either dogs or pigs to consume exposed human bodies, and therefore are very likely animals to be affected.

Pigeons.—Dr. Surveyor, in a private letter to me dated Nov. 13th, 1896, Bombay, asks: "Did you notice any mortality amongst *pigeons* from this disease?" In reply I have to state that I did not, nor did any observer in China, so far as I know, draw attention to the infection of pigeons. If stored grain is the source of infection it is easy to imagine that pigeons would be perhaps one of the most likely species of birds to be affected, and it but draws attention to the disease of grain still more pointedly than before. Several observers in India are most decided in their statements as to the grain source of the disease, and that the rat and pigeon are the sufferers seems to point somewhat in that direction. On the other hand, it must be remembered that the ordinary barnyard fowls are not (except in the London Plague of 1111 A.D., and it is so long ago that it may be discounted), so far as we know, struck down by any disease resembling plague, so that, although the grain origin of the disease may be worth investigating, we cannot turn towards it with any *a priori* hopes of elucidation. It will be seen at once that the infection of birds will render the possibility of the rapid spread of plague on its appearance in isolated districts easily explainable. It is not comfortable news that we have a winged distributor of plague.

To sum up our knowledge, we find that pigs, dogs, rats, snakes, jackals, and pigeons are affected by a fatal malady, whilst plague is epidemic amongst human beings. Pigs and dogs are believed to be attacked only after consumption of plague flesh. Snakes by the swallowing of rats, and possibly jackals, are infected in the same way. None of the purely herbivorous animals, horses, donkeys, oxen, sheep, goats, or rabbits, are attacked. It is the flesh-eating animals which are the sufferers. Of course, the rabbit, guinea-pig, and a number of animals can be inoculated experimentally or made to consume plague-diseased food, but no herbivorous animal acquires it by the natural processes of infection. If it is by consumption of flesh that animals are infected, how do human beings get it? The animals affected seem to become infected from flesh: the snake from the rat, the jackal, pig, and dog from eating the flesh of persons dead from plague; but how does the rat become infected? Could we find that out we should likely know how man is infected. One animal missing in the scale is the cat; if rats perish from plague surely the mortal enemy, the cat, would be diseased. Perhaps the instinct of the cat teaches it to avoid the diseased rat. [In Hong-Kong during 1894 many cats died in a peculiar way—the chief symptom being paralysis of the hind legs.]

In the discussion about the rat infection it must never be forgotten that if we take it for granted that the disease attacks rats before human beings become victims, we must consider the question, "Has the rat ailment to do directly

Hosted by Google

with the subsequent outbreak in man?" It is very difficult to see how the rat could affect man except by *infection;* and one may hesitate to believe, from what we know of the concentration of poison necessary to infect, that such is possible. It might be that the diseased rat, by *treading*, or dropping upon, or biting the food of man, would thereby poison the food. It will at once occur to one that sick rats, like sick men, would not eat. This we have no proof of; in fact, it is the other way, for Dr. Rennie states that in his post-mortem examinations on rats in Canton he found the stomachs pretty full of food, and rats during incubation and first days of illness from experiment eat fairly well. What we may conclude from the study of the infection of animals is: (1) that the rat is the animal most liable to be attacked by plague; (2) that rats suffering from, or dead from plague may infect other animals, such as snakes and jackals, who consume them; (3) that rats are always affected by a disease similar to plague at the same time man suffers; (4) that the rat may infect man, but the means of conveying the contagium is not known; and (5) that during the prevalence of benign plague, pestis minor, rats do not die.

Incubation.—The time intervening between exposure and the development of plague has been carefully observed and noted throughout many epidemics of this century. The conclusions arrived at by all who have written an account of their Hong-Kong experience gives from three to six days as the period of incubation. Dr. Lowson makes it seldom under three or over six. Professor Aoyama gives it at from two to seven days. If by that statement he means from the end of the second until the beginning of the seventh day his recorded observations agree exactly with Dr. Lowson's and others. Only one case seems to break the record: it is a case referred to by both Dr. Lowson and myself. A Chinaman in the gaol at Hong-Kong developed plague after being nine days under lock and key. From June 11th until the 20th he was apparently well, but on the evening of the 20th he became feverish and developed plague. This case gives nine days as the apparent period of incubation and may be taken as the limit in that direction. Dr. Lowson states, however, that the man complained of being ill for two days before being placed on the sick list, thus reducing the period to the seventh day; and although the man was put in the cells on the 11th it was not until the 12th that he was really beyond contact with the outer world. Further, during an epidemic of any kind, isolated cases occurring here and there in the infected centre, where contagion seems difficult to explain, must not be taken as sufficient to seriously arrest attention even when a gaol wall intervenes. An infected area is one in which any dweller may succumb to the disease despite all precautions of isolation. Whilst mentioning this case I do not think we have evidence to place the period of incubation of malignant polyadenitis beyond the end of the sixth day after exposure. Be it observed, however, this extends only to plague infection during an epidemic.

There is a notification of two or three cases of plague as having occurred at the Seamen's Hospital, Greenwich.[3] The following is a statement of the facts: "About the middle of September a man, a Portuguese-Indian steward, was taken into the Branch Seamen's Hospital and died there very suddenly. He was only in about forty-eight hours and no suspicion of plague arose. On the last day in October there was reason to consider that another patient at that time in the hospital was suffering from plague; the previous case was thought of, and it was agreed that if one was plague the other in all probability was of the same nature. The man died; but the medical authorities were not in entire agreement. As a precautionary measure, however, the body was buried in a leaden coffin. The matter was referred for bacteriological examination, the glands of the body were examined, and a bacillus which presented the known characters of the plague bacillus was found." In connexion with this subject there are one or two points calling for comment. 1. The dates given (if correct) would show the vessel, in which the infected persons were, left Bombay about the end of August. Now, we have no direct medical evidence that plague existed in Bombay during August. The earliest official intimation of plague in Bombay was when Dr. Viegas reported, at the meeting of the Sanitary Committee on Sept. 23rd, 1896, that the disease had prevailed in the locality for a fortnight, thereby assigning Sept. 9th as the date of commencement. The first case, therefore, at the Greenwich Hospital could apparently not have been infected from that source, as the vessel could not have been less than seventeen days on the way. Either it is not plague we are dealing with at Greenwich (I firmly believe it is) or the infection must have come from some other source than Bombay; or yet a third condition may obtain, which heretofore we recked not of—namely, an indefinite period of incubation, during which period "benign" plague may become malignant. This subject will be discussed later.

In elucidation of these cases and the source of their infection I think I can throw some light. I stated above that there was no official evidence of the presence of plague in Bombay before Sept. 9th, 1896—that is, ten days after the first Greenwich Hospital patient sailed from Bombay. This, however, may not be quite correct, for I find in the *Times of India*, Sept. 30th, 1896, the following statement:—

"In Bombay for two months certainly, in all probability longer, the native inhabitants of the neighbourhood of Maudvie, when plague broke out in Bombay, seemed to have been alive to the fact of the existence of a malady resembling plague before the malignant type developed. They had organised processions in August to propitiate the goddess of Plague. This either proves that true plague was present long before the authorities knew of its existence or that a disease resembling plague was mistaken for the malignant type." According to this evidence plague may have existed in Bombay in July, 1896. This evidence will, I hope, help those who are dealing with the Greenwich Hospital cases to disentangle the incubation period difficulty. The second case reported from the Greenwich Hospital had been on shore fourteen days before falling sick. Therefore, allowing seventeen days for the voyage, thirty-one days must have intervened between exposure in Bombay and the illness.

The occurrence of several cases of pestis minor in Calcutta, in which the bacillus was found, indicates a more cautious acceptance of diagnosis resting solely on bacillary evidence than we have heretofore contemplated. The first case dealt with and reported upon in Calcutta gives an instructive history. The patient, a lad aged seventeen years, came from Bombay, where evidently he had been exposed to infection, as his sister, who accompanied him, had seen several cases of plague in Bombay. Fifteen days before leaving Bombay he had noticed swellings first in one groin and then in another, but never felt ill until his arrival in Calcutta on Sept. 24th. He was seen and carefully examined in Calcutta by honest observers, and a diplobacterium identical with the Kitasato bacillus was found in his blood. Not only so, but the clinical symptoms of plague were most manifest. It would, therefore, seem from these two well-authenticated cases that glandular swellings may attack a dweller in a district where true plague rages, and that at a subsequent period (a period which in the Calcutta patient was not less than twenty days and in the Greenwich Hospital case could not be under seventeen days) may become virulent and kill the patient by a true plague; in fact, that a pestis ambulans may become a malignant polyadenitis in the same person, even although the patient is removed from the infected zone. This may be true, although it is not at all a comfortable doctrine; but I can come to no other conclusion having regard to the evidence before me. The incubation period of plague, therefore, may be fixed as from three to six days whilst an epidemic rages, but the evidence to hand, within the last few weeks from Calcutta and from London, renders the period of incubation of ambulatory plague uncertain.

Invasion.—The onset of the disease in malignant polyadenitis is known to be usually sudden and severe. The patient is seized with headache, fever, and prostration and compelled straightway to seek his bed. In a few hours or a few days a swollen gland develops and the disease runs its course. But we have on record many cases where high fever existed and the patient did not even feel ill, or where a gland swells up with no general feverish state. Dr. Lowson in his valuable report states: "In one case I took the temperature of an Indian who *looked* ill, but who had merely come to see about the burial of a friend and who complained of no unpleasant symptom. He was rather amused at my using the thermometer, but I found he had a temperature of 103° F. and at the same time discovered a small cervical bubo." Be it observed, as bearing upon the intensity of the virus, that this was a non-fatal attack of plague. In many cases a

[3] Brit. Med. Jour., Dec. 12th, 1896.

Hosted by Google

bubo may precede the fever, the patient suffering no inconvenience even. Such a case is that recorded from Calcutta, where "the patient, a boy from Bombay, had had for fifteen or twenty days before developing fever a swelling in either groin. Subsequently he developed the ordinary symptoms of plague and the diplococcus was found in his blood." These two cases are sufficient to show that fever or plague may exist and the patient not be aware of it, and that glands may be affected for a fortnight before the disease declares itself in the usual way by headache, fever, and prostration. The onset of the disease, therefore, even during a plague epidemic, may not be so definite as we should like to believe, and as yet we have no charts recording the condition of the patient between the time of exposure and the invasion.

Varieties.—It is not my intention to mention merely the varieties of symptoms which predominate at any one time or throughout any one epidemic, but to draw attention to varieties which are so pronounced in their character as to justify the belief that whilst dealing with this subject we are actually attempting to bring in line under one heading diseases which may be even separate species. The commonly accepted types are these: (1) abortive (or larval) plague; (2) typical plague; and (3) fulminant plague. The two latter are so well understood and have been so largely and fully dealt with elsewhere that there is no advantage in recapitulating what can be read in any text-book; but I wish to draw attention to the first-named. The abortive form is sometimes styled larval, ambulatory, or pestis minor. The names partly declare the character of the disease and create a condition so apart that it has at all times been separately described. It is at the same time so indefinite in its duration, so unstable in its relation to malignant plague, and so uncertain in its onset and departure that up to the present no scientific precision has been assigned to the relationships. As long ago as the year 1666, when plague ravaged London, we have it on the authority of Sydenham that "at times tumours may break out without either fever or any important symptoms. . . . Those to whom this happens may walk about in public as usual and attend to the common duties of life. . . ." Foderè, writing of plague in 1820, observes: "In the Levant and in the Marseilles epidemics of 1820 cases were to be seen which were not ushered in by any alarming symptoms and where the natural functions were undisturbed and where buboes and carbuncles appeared without fever or only with slight fever, or the buboes went on to a healthy suppuration more or less prompt, or even disappeared and went on to resolution without the help of art, without any inconvenience, and with a perfect integrity of all the functions. This state is comparable to benign small-pox, during which children play together and walk in the streets without any precautions, no care being taken of their treatment and yet terminating favourably. It is the benign plague of authors which is observed when the disease commences and when it is at its end, though it is rarely seen in the middle period, which is entirely devastating, *but it is not less plague and it no less merits the attention of physicians and magistrates.*" Again, in all recent epidemics in Tripoli, Mesopotamia, and Astrakan non-fatal, mild bubonic disease occurred both before and after the epidemic. We have it on the authority of Dr. Dickson that in Mesopotamia, previously to the manifestation of plague, glandular swellings free from fever prevailed. All this evidence seems to indicate a close connexion between benign and malignant polyadenitis; but we have some evidence of the separate existence of the two diseases. 1. In Mesopotamia Tholozan records: (*a*) that mild non-fatal bubonic plague existed from 1856 to 1865, during which period (nine years) no malignant type was observed; and (*b*) that after the epidemic of malignant plague (1866-67) passed over the same form of mild plague existed. Did it exist during the epidemic? This is not known, for it is not likely that persons suffering from so mild an ailment would present themselves for treatment to foreign medical men at a time when all swellings were viewed with suspicion. There is, therefore, no evidence to show that the two diseases did not co-exist seeing that it existed nine years before and perhaps as long afterwards. The present belief is that the mild develops into the malignant type, and when that subsides it is once more deprived of its malignancy and becomes benign. We have no evidence of any disease behaving in such a manner to such an extent as claimed for plague. 2. In Calcutta six years ago an outbreak of mild, non-fatal plague occurred in the fort amongst the troops, but it was not followed by the malignant variety. 3. At the present moment in Calcutta there is reported to be a form of fever with glandular swellings, and also a form of glandular swellings without fever, and it is further stated that these are constantly met with in medical practice in Calcutta. 4. In 1890 the variety of idiopathic buboes, of glandular swellings with fever, and of mumps met with in Hong-Kong before referred to was not followed until four years afterwards by plague. These records go to prove:—1. That long periods of time may intervene between the prevalence of specific glandular swellings and the outbreak of malignant plague. 2. That glandular swellings may exist for nine years before malignant plague appears, and continue for years after it has disappeared. 3. That independent outbreaks of glandular swellings (pestis minor) may come and go and no plague supervene.

The latest evidence we have from Calcutta is conflicting in the extreme. We have it to hand on trustworthy evidence that people are suffering from fever with glandular enlargement, that the disease is regarded as pestis ambulans—a mild bubonic plague—and that *the diplo-bacteria of plague are found in the blood.* We have hitherto regarded the presence of the bacillus in the blood as the one token of the disease being malignant in type; but we have now contrary evidence to consider, and if we are to accept it, we must believe that specific glandular swellings in the plague belt may be caused by a definite bacillus, and at the same time admit a varying degree of malignancy to that bacillus. Professor Cunningham—a most competent observer—declares that the bacillus found in the Calcutta cases is non-infective, and that probably it is not the same bacillus as that described by Kitasato in 1894. This is stated in the face of positive evidence by careful observers which cannot be set aside thoughtlessly. Time alone will answer this question. In the meantime, however, it is feasible to suggest that there may be but one bacillus, and that according to its state of development, or in consequence of its evolution, different types of the disease may prevail in the human body, each associated with a definite train of symptoms, characterised in the one by glandular swellings merely and in the other by a toxic infection of extreme intensity.

The bacillus. — The bacteriology of plague began with the advent of Kitasato from Tokio during the Hong-Kong epidemic of 1894. On June 14th, 1894, Kitasato demonstrated the bacillus, which was confirmed afterwards by Dr. Yersin of the Pasteur Institute in Saigon, working in an independent manner. The bacillus has been variously described as (1) a diplococcus; (2) diplococcus enclosed in a delicate capsule; and (3) a short bacillus with the ends somewhat rounded and a clear space or band in the centre. Professor Woodhead writes:—"The size varies considerably according to the staining method employed, the organism appearing rather smaller in the watery gentian violet solution than in the glycerine fuchsin solution. It is plain that the size of the capsule and its staining capacity vary very considerably, and it is quite possible that this appearance of a capsule is like that which is sometimes met with around the bacillus of anthrax stained in special solutions in that it may be simply a refraction from the albumin from the constricted bacillus due to the drying and other processes of preparation." In the figures drawn by Woodhead an organism was met with in some specimens which seems to indicate a development after death. The last statement may be the most important of all, and its confirmation will be anxiously looked for during the present outbreak in India. It may be the first step towards a knowledge of the life-history of the bacillus in the same manner as the flagella of the plasmodium malaria are found to develop in the field of the microscope some half hour after removal from the body. Dr. Yersin undertook some experiments to test the truth of the infection of the soil, the results of which elucidate the toxic nature of the bacillus. He found (1) that a bacillus in some respects resembling in its appearance that met with in the human body was found in the soil of Hong-Kong during the plague epidemic; (2) that the bacilli of the soil and body occasionally behaved similarly in culture experiments; and (3) that the culture specimens of soil bacilli were, however, innocuous, possessing no virulence when injected into mice or guinea-pigs. Dr. Yersin further found that in his cultures of human plague bacilli there were microbes of different virulence, some mildly powerful and some altogether powerless to infect either mice or guinea-pigs. Dr. Lowson, in conjunction with Dr. Takaki, Dr. Kitasato's assistant, found a

Hosted by Google

bacillus in the soil of the garden near his house which closely resembled the human plague bacillus, possessing most of its microscopic attributes, but showing none of its toxic properties. The district whence the soil was obtained lay within the plague-stricken area, but considerably removed from any infected house.

The conclusions to be deduced from the above rehearsal are:—(1) That plague bacilli vary in size; (2) that cultivation experiments produce bacilli identical in appearance but possessing different toxic and infective powers; and (3) that a somewhat similar bacillus is found in the soil (whether at all times or not is not known) which resembles the non-virulent form the result of bacteriological culture.

Infection of the soil.—The preceding remarks upon finding the bacillus in the soil are pregnant with suggestion. Whether the soil bacillus be virulent or not, whether it be completely identical with the human bacillus met with in plague or not, the fact of a microbe having on the one hand a close resemblance microscopically and on the other hand a structure and behaviour analogous with certain of the non-virulent culture products of human plague bacilli, is sufficiently important and brings the elucidation of the matter within the sphere of practical investigation. The dominant idea before even the bacteriologist or microscopist studied the matter was that the infection arose from the soil, and there seem no facts to go upon to reject the creed. The Chinese grade the scale of animal infection by their height from the ground, and the modern scientist lends some weight to the suggestion. The medium of the soil may be to the infection of animals as the medium of water bearing the carcase of the dead mosquito is to the filarial-infected human being. Not only may it serve as a mere vehicle, but as a host, in which the parasite passes through a stage of its evolution. Bearing closely upon this subject is the question of the *medium* of spread of plague. I previously discussed this shortly when dealing with contagion. Contagion—that is, intimate prolonged contact, as mother or nurse and child—no doubt is a factor, a potent factor, it may be the only factor, in the transmission of the disease, but few admit it to be more than a small element in distributing plague broadcast over a community. The slow progress of plague and its peculiar paths of selection must be considered if the subject is to be fairly dealt with. Plague is perhaps the slowest travelling disease known; it may take months and even years to extend a few miles. From the City of London it took nine months to reach Soho, and more recently it took ten months to travel from Hong-Kong to Macao—a distance of thirty miles. The lines of communication will not explain this, for in Macao thousands of persons sought shelter in 1894, when Canton and Hong-Kong were plague-stricken. Steamers and Chinese junks and fishing-boats passed freely between the ports, yet Macao did not become infected until nine months after Canton and Hong-Kong were pronounced clear. How did the parasite reach Macao—by sea from Hong Kong or by land from Canton? If by sea, in all probability it would have been in Macao long before. If by land, how did it travel—by human or animal carriage or by the soil? If by human beings, it means intimate prolonged contact of the carriers, if by the soil it means a bacillary infection of the soil, spreading from a centre and extending by a continuous margin of active growth along paths favourable to its nutrition. As a gangrene spreads from a centre, or a patch of ringworm starts to spread and gradually involves an ever-increasing zone, so may the soil become sown with the germ of plague, and animals that have their habitat thereon fall victims. Some show of testimony towards such a view is afforded by the fact that plague confines its working to the Old World and does not cross the ocean, and travels backwards and forwards in the belt of its selection; but it cannot be the only means of travel, otherwise how did the islands of Britain and the Canaries ever become infected at one end of the Old World and the islands of Hong-Kong and Formosa at the other? Were the soil only the producer or infector all islands in the area ought to be immune. This not being so, it comes that the poison must be carried by human beings, by animals, by clothing, or by food. That the poison conveyed by them may require the soil as a medium to reproduce the infecting bacillus may be quite possible; but that some other medium than the soil capable of transmitting the disease is quite evident. is As noticed above, the bacillus found in the soil, according to Dr. Yersin, agrees in most points with the plague bacillus except that when introduced artificially into the bodies of animals it is non-virulent. This may indicate, of course, that they belong to another group of the bacterial family altogether.

THE ACCOMPANIMENTS OF PLAGUE.

Climate—The weather does not escape blame for a share in the presence of plague when it rages in the midst of a community. Be it dry, the drought is mentioned as a cause; be it wet, the floods which ensue are held to have damaged the crops and the grain supply is spoiled, or the miasm resulting from the subsidence of the swollen streams is connected with the outbreak. In south-east China the epidemic of plague developed at the end of a prolonged and exceptionally dry season. The rainfall was so deficient that most of the wells throughout the district were exhausted, and the crops suffered severely. Without driving the argument of drought too deeply home it must, however, be observed that in Bombay we find a similar condition of things before the present outbreak. The rainfall over a wider area of country has been so greatly deficient that widespread famine has followed. Without recording any more examples we must consider whether there is any probability of connexion between drought and plague. The bacillus of plague flourishes best in a warm, moist atmosphere; dry, hot air kills it. In many marshy countries, however, the epidemic has been found to disappear the moment the rain ceased and the dry season set in. In Mesopotamia and in Egypt the epidemic dies out in summer, when the nights and days are more alike in temperature, and the fall of dew is therefore less pronounced. The absence of rain means, of course, dirt in the houses, in the streets, and on the clothes and bodies of the inhabitants; and dirt is held to be the foster-parent of plague. But the absence of rain means dryness of soil, and if the bacterium is dependent on a sufficiency of moisture it would seem as though a small quantity satisfied it.

Rain.—In Hong-Kong it was hoped in 1894 that with the advent of rain the epidemic would abate. The rains delayed their onset until well on in May, by which time the epidemic had got a hold in the town. With the rains came an accession—a marked accession—of the number of plague cases. The flushing of the drains and gutters and the replenishing of the wells with a plentiful supply of water were attended by an increase in the outbreak. Before referring this positively to the effect of procuring a more moist nidus for the bacillus to develop in, the effect of rain on the habits of the people has to be noticed. In all warm climates a number of the male portion of the inhabitants sleep out of doors—on the roof, in the street, or in verandahs. The effect of rain is to drive all such sleepers within the house, to shut the windows and doors, and to generate all the evils of overcrowding. The good effects of the flushing of sewers are undone, in the opinion of the climatological argument, by the overcrowding which it causes.

Heat and cold.—In Canton the plague commenced when the temperature averaged about 60° F. and continued when the average daily temperature reached 90°. Further, it must be noted that the disease *disappeared* when heat and moisture were about 90° throughout the district, so that with regard to the common statement that it thrives best at a temperature between 80° and 85°, it must not be forgotten that whilst thriving it also disappears at the same temperature. It dies out when the conditions which we believe to be suitable for its propagation, heat and moisture, are at their best. But heat does not seem to be an essential to the appearance of plague. In Russia it has appeared again and again in winter with deep snow on the ground and the thermometer in the neighbourhood of zero. In Astrakan in 1878 the disease raged during severe winter weather. We are at a loss, therefore, to connect warmth with plague or cold weather with its check. We may experimentally show how the bacillus behaves under the abnormal medium which must necessarily surround it in the microscopic field, but that in its natural state it is so affected we have direct antagonistic proof.

Overcrowding.—The argument of overcrowding might be at once set aside by the sweeping statement that just as plague flourishes in crowded cities, so likewise it flourishes in barren deserts, where the population is sparse in the extreme. An analogous disease, typhus fever, behaves in well-nigh the same way, and typhus fever is looked upon as the direct outcome of overcrowding. Now overcrowding may take place in a country house as readily as in a town house, and the

Hosted by Google

poorer the country the greater the overcrowding. Typhus fever prevails in isolated houses on the west coast of Galway, where the air around is of the purest; but eight or ten people or more in one room, not only sleeping there for warmth but residing there well-nigh all day when the weather is inclement in winter, will foster any disease that foul air is capable of producing. As with typhus fever, so with plague. The rains in warm climates drive the inhabitants within their poor dwellings, the snows of winter do the same in colder climates, and the ailments attending overcrowding are most likely to appear. In other countries, as in Mesopotamia, the cessation of rain brings the cessation of plague, as the people can issue forth to sleep and open their casements without fear of being drenched. The close, intimate contact believed to be necessary for the propagation of plague is therefore brought about by two entirely opposite conditions which have overcrowding in common; and taking all the effects of weather into consideration it would seem that not the meteorological conditions but the mechanical results of weather generally are to be reckoned with. Castaldi's account of a dwelling-house in the highlands of Kurdistan, where one might expect that fresh air would be plentiful and overcrowding unknown, confirms the above statements. "Whatever is most afflicting in poverty, whatever is most revolting in filthiness, is accumulated as if designedly around these infected dens in the interior of which live—or rather vegetate—from fifty to sixty men, women, and children." Perhaps the effects of overcrowding are more frequent in the colder latitudes of Western Asia and Eastern Europe than anywhere else in the world.

Poverty.—Plague is ever associated with scarcity and want. Sometimes it is famine caused by the destruction of crops by floods, sometimes by drought; but from whatever cause plague and scarcity of food are frequently allied. Not only is the grain scarce, but it has often been commented upon that it is bad, musty, covered with blue mould, and fermented. The two conditions may be to each other as cause and effect. The grain is gathered before it is ripe owing to the people's necessity, and the unripe grain not only yields insufficient nourishment but is apt to undergo fermentation and be attacked by vegetable parasites. In South-East China there was no question of famine before the 1894 outbreak, but the price of grain was high. This was caused by the prolonged drought in the district and by the failure of the crops in Siam—Bankok, the capital of Siam, being the chief source of rice supply to Canton and district. The rice was subsequently obtained at a fairly cheap rate from Saigon, the capital of Indo-Chine, and the price of grain fell. In India at the present moment a serious scarcity prevails and famine threatens. The prolonged drought is the cause of the failure of crops, and, moreover, the consumption of diseased grain is universal. Three elements are in evidence—drought, famine, and diseased grain; but they are really co-partners and inter-dependent. No one can be upheld as the cause to the out-voting of the others. It may be none of these have aught to do with the presence of plague, as it may be argued plague exists when famine is unheard of; but the combination which also means overcrowding of houses must be a factor, if not the chief factor, in the propagation of the disease. In the towns, and in the poorest parts of the towns, would be the most likely spots where the combined effects of want and overcrowding would show; and it is invariably in such neighbourhoods plague develops and stays. In the densely packed cities of Asia the poor exist for ever on the fringe of destitution and the least rise in the price of food brings scarcity, so that the term "the poor's plague" holds good for all time.

Sanitary conditions.—The preceding remarks prepare the way for the recognition of all possible sanitary evils and neglects as accompaniments of plague. Chinese towns are at all times ready to generate any filth disease and Hong-Kong itself is but little better. The city was hastily built about fifty years ago, when all too hurriedly tens of thousands of Chinese sought occupation and habitation under the British rule. From that rush of people and feverish haste to build without proper control the city never recovered, and to this day presents sanitary aspects of the most flagrant description. The public sewers are well built on the separate system; the water-supply is most excellent in quality, although, when rains are delayed, deficient in amount; the public latrines are under Government control; the removal of excreta is by the bucket system and is admirably controlled. Here, however, the bestowal of praise must cease, for beyond them there is much to condemn. House overcrowding is rife and surface crowding to the extent of 2500 persons to the acre holds sway over the chief area of the native quarter of the town. Dr. Lowson states graphically what is known to every resident in Hong-Kong: "The majority of the houses of the infected district being in a most filthy condition . . . when to a mixture of dust, old rags, ashes, broken crockery, moist surface soil, &c., is added fæcal matter and the decomposing urine of animals and human beings, a terribly insanitary condition of affairs prevails." At another part of his report Dr. Lowson remarks: "To over-paint the pitiable surroundings associated with plague work at the commencement of the epidemic would be impossible. I have entered a long low cellar, without any window opening, and with the air entering only by a square open shaft from the level of the roof three or four storeys high. Down one side of the shaft ran a broken earthenware drain-pipe leaking freely, the contents streaming down the wall of the air shaft to a shallow pool of filth which crossed the undrained floor of earth. Although it was broad daylight outside a lantern was necessary to see one's way. On a miserable sodden matting soaked with abominations there were four forms stretched out. One was dead, the tongue black and protruding. The next had the muscular twitchings and semi-comatose condition heralding dissolution. In searching for a bubo we found a huge mass of glands extending from Poupart's ligament to the knee-joint. This patient was beyond the stage of wild delirium. Sordes covered the teeth and were visible between the parted and blackened lips. Another sufferer, a female child about ten years old, lay in the accumulated filth of apparently two or three days, unable to speak owing to the presence of enlarged cervical glands. The fourth was wildly delirious (the conjunctivæ intensely congested) and was constantly vomiting. The attendant (*sic*), the grandmother of the child, had a temperature of 103° F. and could only crawl from one end of the cellar to the other. She was wet through and was herself doomed. This is no fancy sketch, but a true picture of how we found some of our patients at the outbreak of the scourge in Hong-Kong." The evidence from Bombay is similar to the Hong-Kong report, and but confirms the state of overcrowding and filth to which Oriental cities, even when partially under British control, may attain.

Caterpillars.—At the time the plague broke out in Hong-Kong and Canton the district was infested by a caterpillar which covered the trees in myriads and destroyed the foliage of many. So threatening was the pest that the Colonial Government in Hong-Kong granted a reward of so much per basket to the collectors of these animals. The accident of their presence may be fortuitous merely and have nothing to do with the presence of an infective bacillus; but there can be no doubt that the destruction of plant life on the mainland of China from this cause had to do with the high price of grain which prevailed at the time plague broke out.

Diseased grain.—That one is justified in looking to grain as a source of infection we have collateral confirmation from other diseases arising from grain. 1. Ergot of rye—the mycelium of Claviceps purpurea infecting common rye—is capable of producing epidemics attended by a great mortality. In France, Russia, and Sweden, even during the present century, outbreaks of what the Germans style "Kriebelkrankheit" have occurred. 2. The pellagra of Lombardy is a disease of modern times, but corresponds closely in time with the introduction of an inferior kind of maize as the staple food of the peasantry. This disease is at times epidemic, and although it can be traced to want of care in the drying and preparation of the grain, once it breaks out in a neighbourhood it takes hold of members of the community who feed on the best kind of materials. 3. Acrodynia has so close a resemblance to ergotism and pellagra that it is presumed to be connected with bad grain, although the connexion has not been traced. 4. Pelade—a disease met with in Columbia, South America—is traced to the ergot parasite of maize. 5. Actinomycosis is due to a fungus—probably of the order Cladothricæ,—is even better known than either of the preceding, and the general evidence is that it is introduced with the food. 6 In the uplands of Kurdistan the four following conditions co-existed or followed in sequence during the 1870-71 outbreak: (1) bad grain; (2) ergotism; (3) epizootic amongst sheep; and (4) plague. 7. At the present moment in Bombay diseased grain is plentiful, and it would seem that Dr. Watson has succeeded in proving a connexion

Hosted by Google

between plague and diseased grain. With the help of modern methods of investigation and the accumulated knowledge of the disease gathered during the last few years the matter should not be difficult to settle. These instances might be multiplied, but they are sufficient to show that the search for the cause of plague in grain is not a blind hunt, but has creditable precedents.

Differential diagnosis.—In all cases nowadays the microscope is regarded as the one test whereby to test the presence or absence of plague. Rightly or wrongly this conclusion has held good ever since Kitasato discovered the bacillus in June, 1894. The names given in an earlier part of the paper indicate the diseases held to be closely analogous to plague. They are "typhus," "adynamic typhoid," and "intermittent fever"; but the word "bubo" is affixed to all. Still the name gives the drift of its applications and enables us to apportion its place in the category of disease.

Typhus fever.—The resemblance to typhus fever, in many signs, symptoms, methods of spread, and circumstances of development, is worthy of more than a passing remark. It has been noted how overcrowding, whether in town or country, is a potent factor in plague as in typhus fever. Hæmorrhages—so characteristic of typhus fever—are so frequent in some outbreaks of plague as to occasion the use of the synonym of "hæmorrhagic fever." The infectious nature of the two diseases appears so similar, so markedly "catching" to all inmates of an infected house, so sparing in their seizure of visitors. Such instances of the resemblance between the diseases might be multiplied with the result that we might become converts to the opinion expressed by Murchison that "Plague is perhaps the typhus of warm climates, the two diseases being generated from similar causes and differing only in intensity from the effects of climate and other collateral circumstances." The specially characteristic sign of plague is the presence of buboes; the specially determining sign of typhus fever is the rash. Both may be absent in either; or we may find buboes in typhus fever and petechial eruptions in plague. The eruptions met with in the Hong-Kong epidemic were never characteristic, although many cases showed spots on the skin. These in most instances were no doubt mosquito bites, but the occurrence of a pink blush around them gave a specific appearance to these petechiæ. Further, the distribution of typhus fever corresponds in many ways with that of plague. Typhus fever has a southern limit, not being met with within the Tropic of Cancer in either the old or the new world. Typhus fever has never reached Australia or New Zealand, or appeared south of the Equator. Typhus fever, however, is accredited to have reached the United States and Canada, where plague has never been. With this solitary exception the distribution of the two is synonymous. The pursuance of this subject would lead me far beyond the limits of time at my disposal; but there can be no doubt that we have two diseases generated by a common cause, overcrowding and personal filth; and, if we assume the supervention of a specific microbe upon such states, typhus fever or plague, as the case may be, may arise.

I have yet another disease to add to the list which may be mistaken for plague. On June 26th, 1894, when the plague was at its height, I saw a Parsee patient dwelling in a house in which plague existed, suffering from fever (104° F.) dry tongue, headache, backache, and large swollen glands in the left groin which had suddenly appeared. Plague seemed the only diagnosis, and the man, much against his will, was sent to the plague hospital. In two days he came back again quite well, and on examining him I found his urine thick and milky. That night I found filaria in the man's blood, and knew I had made a mistake in the first instance. Of course, the mistake is most likely to happen, but nevertheless it is not pleasant to think that we had subjected the man to the terrible danger of plague infection.

The conclusions drawn from a study of the spread of plague are:—I. Varieties: 1. The varieties of plague known under the names (*a*) fulminant, (*b*) typical, and (*c*) pestis minor, are allied. 2. The cause of fulminant and typical plague is a diplobacterium in the blood and tissues. The cause of pestis minor may be an allied diplobacterium, but with a lesser toxic power. 3. An appropriate name for the fulminant and typical plague is "malignant polyadenitis." An appropriate name for the mild variety (pestis minor) is "benign polyadenitis." II. Infection and contagion: 1. Plague is infectious chiefly by the dust arising during the cleansing of dwelling houses which plague patients have occupied. 2. Plague is contagious by prolonged and intimate contact with the plague-stricken, as in the case of a nurse carrying a child ill of the disease. III. Distribution: 1. Plague is met with in a definite area of Asia which may be termed the "plague belt." 2. That the home of plague at the present day is Mesopotamia and the countries adjacent. 3. From Mesopotamia as a focus the plague may spread northwards to the Caspian Sea, westwards to the Red Sea, southwards as far as Bombay, and eastwards as far as (Formosa) the China Sea. 4. During the present century plague has shown a western retrocession and an eastern accession of virulence. IV. The bacillus. 1. Typical plague (malignant polyadenitis) is associated with pestis minor (benign polyadenitis). 2. A bacillus of somewhat similar appearance microscopically is reputed to be found in both.[4] 3. The bacilli differ in their toxic powers only (?). 4. A benign polyadenitis may run its course without being preceded or followed by the malignant variety. 5. Malignant polyadenitis may run its course without being preceded or followed by the benign variety. 6. The bacillus of the benign variety attains malignancy by passing through some intermediate host, possibly, but not probably, the rat.

NOTES ON STONE IN THE BLADDER.

BY D. F. KEEGAN, F.R.C.S. ENG.,
BRIGADE-SURGEON-LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE (RETIRED).

I.—LITHOLAPAXY IN GIRLS AND WOMEN.

THE great majority of vesical calculi which are met with in girls and women are best removed by litholapaxy. I take it for granted that no one nowadays would dream of employing the ancient method of rapid dilatation of the urethra, with subsequent extraction of the calculus, if called to treat a young girl the subject of stone in the bladder, unless, indeed, the calculus were a very, very tiny one. Dilatation of the urethra with extraction was always a somewhat rude surgical procedure even in adult females, but there was much to be said for it in the days which preceded Bigelow's brilliant innovation in the treatment of stone in the bladder. Any surgeon, however, who at the close of the nineteenth century adopts as a routine practice the old method of rapid dilatation of the female urethra with extraction is behind the age and is hardly to be tolerated. There remain two other methods of removing a stone from the female bladder—viz., vaginal lithotomy and suprapubic lithotomy; but the cases in which they should be employed are few and far between. In most surgical text-books the subject of vesical calculus in the female is usually dismissed in a very cursory and somewhat perfunctory fashion. The scanty attention accorded to it is in some measure due to the fact that stone is so rare in girls and women as compared with its frequent occurrence in boys and men, and partly to the ease and safety with which a stone is removed from the female bladder as compared with the difficulties and dangers which surround its extraction from the male bladder. It falls to the lot of very few surgeons in Europe to treat many females for stone in the bladder, and hence few are warranted in expressing any very decided opinion as to the comparative advantages of the different methods of dealing with stone in females. Mr. Cadge, in his admirable lectures on the surgical treatment of stone in the bladder delivered at the Royal College of Surgeons of England in June, 1886—lectures, which, by the way, everyone interested in the surgery of the urinary organs would do well to study—stated that in 1125 operations for stone in the bladder at the Norwich Hospital there had been only 50 in females, and that in his own experience of 300 cases of vesical calculus he had only met with six in the female. Surgeon-Lieutenant-Colonel Freyer in 864 cases of stone in the bladder has met with only 17 cases in females. Brigade-Surgeon-Lieutenant-Colonel Forbes Keith amongst 1993 cases of stone in the bladder which came under his care in the Civil Hospital, Hyderabad, Sindh, treated 57 cases in females. During the last fifteen years about 900 patients have been admitted into the Indore Hospital, Central India, for stone in the bladder, and there were but 20 females amongst this number. From

[4] This is under discussion now (Dec. 18th, 1896).

Hosted by Google

these figures, which are sufficiently large to warrant safe deductions, we may conclude that stone in the bladder is about thirty times as common in the male as it is in the female. Appended is a table giving the particulars of the twenty cases of stone in females admitted into the Indore Hospital, and a glance at it will show that 18 out of the 20 were treated by litholapaxy. The last three operations recorded in the table were carried out since I left India. To show what an eminently satisfactory operation litholapaxy is in females of all ages I will very briefly give the histories of some of the more interesting cases in this series.

TABLE I.—SHOWING PARTICULARS OF TWENTY CASES OF STONE IN THE BLADDER IN FEMALES TREATED IN THE INDORE CHARITABLE HOSPITAL, CENTRAL INDIA, BETWEEN MARCH, 1882, AND DECEMBER, 1895.

No.	Age (years).	Caste.	Date of operation.	Nature of operation.	Time occupied by operation in minutes.	No. of lithotrite used.	No. of catheter used.	No. of times lithotrite was introduced.	No. of sittings.	Composition of stone.	Duration of disease in months.	Weight of stone in grains.	Number of days in hospital after operation.

* Successful. † Relieved.

CASE 5. — A Brahmin girl aged four and a half years was brought to the Indore City Dispensary on Oct. 17th, 1887, suffering from complete retention of urine. Her friends gave the following history: "The girl has laboured under stone symptoms for the last two years, and latterly these symptoms have become aggravated, so much so that she cries and rolls on the ground from paroxysms of pain at each effort of micturition; passes urine about thirty times in the twenty-four hours; was seized with retention of urine early this morning." The native assistant at the dispensary, finding the stone firmly wedged in the urethra, at once sent the girl to me at the hospital. Chloroform having been administered I returned the stone into the bladder with some difficulty, and easily disposed of it by means of a No. 6 lithotrite, which I passed into the bladder twice. A No. 10 evacuating catheter passed readily into the bladder and the operation lasted twelve minutes. The stone, a mulberry one, consisted of oxalate of lime and uric acid and weighed twenty grains. Next day she was walking about the ward of the hospital, and the day after she had no urinary symptoms and passed urine seven times in the twenty-hours. She went home on Oct. 21st, having been in hospital only four days. These mulberry calculi grow very slowly as a rule. Nearly half of this patient's young life had been spent in pain and misery. For how much longer she might have suffered had she not been seized with retention of urine it is difficult to surmise.

CASE 6.—A Rajput girl aged three years was admitted into hospital on Oct. 29th, 1887, with well-marked symptoms of stone in the bladder of one year's standing. Her condition was most pitiable. She was thin and anæmic. For six months she had suffered from great irritability of bladder accompanied by prolapsus ani at each effort of micturition, having no rest at night, and passed urine about forty times during the twenty-four hours. On Oct. 30th I placed her under the influence of chloroform, and passing in a No. 6 lithotrite seized a large stone readily. The bladder resented the presence of the lithotrite and spasmodic contraction of the viscus was very violent, although she was

Hosted by Google

deeply under the influence of the anæsthetic. A No. 8 evacuating cannula passed readily into the bladder. Whilst working the lithotrite and aspirator my assistant pressed the wall of the urethra against the instruments so as to retain as much urine in the bladder as possible. Nevertheless, a good deal of fluid leaked out of the bladder. I was obliged to use the lithotrite on six separate occasions, and after three-quarters of an hour's work I had extracted the entire calculus. The débris, when dried, weighed 183 grains, and consisted of phosphates and a small nucleus of oxalate of lime. The straining and the very irritable state of the bladder made the operation a very prolonged one. The after history of this case was briefly as follows. On Oct. 31st the patient did not cry when passing urine; there was no prolapse of the anus; she slept well, had passed urine seven times since the operation, and had wetted her bedclothes. There was no pain on pressure over the region of the bladder. On Nov. 1st the morning temperature was normal. The patient had slept soundly during the night. On the 2nd she ate well and had sound sleep, had full control over the bladder, and passed urine eight times in the twenty-four hours. On the 3rd she played about the hospital grounds and seemed quite happy. The change in her condition in so short a time was very remarkable. Her mother took her home in the evening.

CASE 8.—A low-caste Hindu brought his daughter aged seven years to the Indore Hospital on March 12th, 1889, suffering from very urgent stone symptoms. She had suffered for two years and as she had lost control over the bladder was in a very miserable condition. She was at once placed under the influence of chloroform, and I struck a large, soft stone, which I crushed with a No. 6 fully fenestrated lithotrite. The lithotrite was introduced on nine separate occasions owing to the straining of the bladder. No difficulty was experienced in passing a No. 14 evacuating catheter, and on two occasions I passed a No. 15 straight catheter, to which I attached a Berkeley Hill's aspirator. The débris weighed 225 grains and the operation lasted fifty-seven minutes. The girl resided in the city of Indore, and her father took her home the same evening much against the advice and wishes of my assistant, saying, as he left the hospital, that he could not afford to spend any more time on his daughter. If his son had undergone a litholapaxy he would doubtless have spent three or four days in looking after him in the hospital. After all, there is much to be said for woman's rights, and even something for the new woman. My assistant paid the girl a visit four days after the operation and found her playing outside her hut. She had regained perfect control over the bladder and was perfectly well.

CASE 16.—A young woman aged eighteen years, a Bhîl by caste, came to the Indore Hospital on July 28th, 1893, with urgent symptoms of stone in the bladder, which had existed for three years. I broke the stone—a hard one—with a No. 15 lithotrite and finished the operation by means of a No. 13 and a No. 8 lithotrite. Evacuating catheters, Nos. 15, 16, and 17, were employed. The patient strained violently during the greater part of the operation and the fluid in the bladder was rapidly expelled, although my assistant pressed the urethra against the lithotrite while I continued the crushing process. I was compelled to introduce the lithotrite into the bladder on nine different occasions and the operation was therefore a prolonged one, lasting seventy minutes. The débris consisted of fawn-coloured uric acid, and when dry, next day, weighed 702 grains. There were no untoward symptoms of any kind after the operation and she remained only five days in hospital.

There are but two cases in the table appended which were not amenable to litholapaxy and their histories are briefly the following.

CASE 7.—A weak anæmic woman was admitted into the Indore Hospital on June 1st, 1888, with symptoms of stone in the bladder of three years' standing. She gave her age as thirty, although she looked more like fifty years. During the previous six months she had suffered from constant dribbling of urine and her life was a burden to her. Next day, having been placed under the influence of chloroform, a stone was found bulging into the vagina. On passing a small steel sound into the urethra it at once impinged on the stone, which was pressing against the meatus. I tried to pass a small lithotrite, and in endeavouring to do so the urethra gave way at the meatus and the rupture extended backwards for half an inch, so thin and weak had the urethra become by the constant pressure exerted on it by the stone. I therefore extended the rupture by a clean cut of a scalpel for another inch, which included the neck of the bladder, and exposed the stone, which I then found was tightly grasped by the bladder and was perfectly fixed in position. I now endeavoured to crush the stone with a large lithotrite, but this I found not feasible, as there was no room in which I could work the instrument. I accordingly extracted the stone by means of an ordinary lithotomy forceps, but this I accomplished with very great difficulty. Indeed, I was obliged to peel the bladder from the stone by means of a broad director, while my assistant made traction with the lithotomy forceps, so intimately united were the bladder and stone. On extracting the calculus, which weighed 1140 grains and was composed of phosphates and urates, I found it to be a perfect cast of a very contracted female bladder, and on the inferior and posterior aspect of the stone were two well-marked deep depressions, or blind holes, corresponding to the openings of the ureters into the bladder. I then washed out the bladder with an irrigator and brought the margins of the incision together with stout ligatures. The after-history of this case was as follows. On June 4th the ligatures were in position; the wound looked healthy; and urine passed drop by drop. On the 8th one or two of the the ligatures near the meatus had given way; the remainder of the incision co-apted well. On the 13th the greater part of the incision was well joined; there was some gaping near the meatus; the dribbling of urine was much less. On the 16th the patient had more control over the bladder; the anterior portion of the wound in the urethra was refreshed by the scalpel and new sutures were introduced. On the 19th the urine could be retained for two hours at a time. The patient, however, occasionally passed a small quantity of urine involuntarily. On the 22nd urine was passed voluntarily three times during the day and twice during the night. There was no dribbling of urine during the day time, but sometimes a few drops of urine were passed in her sleep. The patient's health was much improved. On the 24th the urine could be retained for four hours at a time and was passed only twice during the night. The patient's husband, who accompanied her to the hospital, insisted on taking her home as the monsoon had set in and he was obliged to look after his fields and the sowing of crops. The patient promised to return to the hospital in a month's time. As a matter of fact this woman never did return to the hospital for treatment, but I have little doubt that she ultimately regained perfect control over the bladder. I question very much if a suprapubic lithotomy would have given any better results than those which followed the operation I was forced to perform. A suprapubic lithotomy in such a case would have been a very difficult operation, for no water could have been injected into the bladder, and fixed as the stone was there would have been considerable danger of wounding the peritoneum in extracting it by the suprapubic route. Indeed, the peritoneum in a case of this kind, where the size of the bladder had been reduced to the dimensions of a small pear, would have descended much lower than it usually does. I showed the calculus removed from this patient's bladder to the Fellows of the Medical Society of London in March, 1891, and a more perfect specimen of its kind does not exist.

CASE 9.—A Hindoo girl aged seven years was admitted into the Indore Hospital on April 19th, 1889, in a most miserable condition, suffering from stone in the bladder and incontinence of urine. Her mother, who brought her to the hospital, stated that the girl had suffered from stone symptoms from her infancy. Placing her at once under the influence of chloroform I found the calculus sticking in the meatus of the urethra. There was a large hole in the bladder into which I could readily insert my index finger. This hole was about an inch from the meatus. I therefore slit up the urethra, and seizing the stone with a lithotomy forceps endeavoured to extract it. In doing so the stone, a phosphatic one, parted in two, and the anterior half came away in the jaws of the forceps. The posterior half of the stone I found firmly attached to the bladder wall and I removed it by means of the scoop and forceps. The bladder and vagina were well washed out by an irrigator and she was removed to bed. The stone weighed 335 grains—a large one for a child of her age. Her health improved after the operation, and with care and rest and good feeding she rapidly grew plump. On May 24th I performed an operation for vesico-vaginal fistula. Such operations in young girls are extremely difficult owing to the limited space

Hosted by Google

afforded for manipulating instruments, and in order to give myself more room I divided the perineum almost to the anus. Silver wire sutures were employed; a gum elastic catheter was retained in the bladder, and the legs were tied together with bandages. On the 27th the perineal incision and wounds of the urethra and bladder had seemingly healed. Urine was passed by catheter. On the 30th the patient's health had much improved; when the catheter was removed for a few minutes there was dribbling of urine. On June 3rd the catheter was removed for an hour; meanwhile, urine was passed by stream. On the 9th the sutures were removed; urine passed by stream, and the catheter was removed for good. On the 13th the urine could be retained for half an hour, and then was passed by stream, but a few drops came by vagina. On examination it was found that a pinhole existed in the vesico-vaginal septum. The patient's mother, becoming weary of staying in hospital, took the child home, promising to return some months later. She, however, did not keep her promise. Bearing in mind the child's age I am inclined to think that she ultimately made a complete recovery, but to be on the safe side I have noted the result as "relieved" and not successful.

To recapitulate; adding together Surgeon-Lieutenant-Colonel Freyer's cases and those admitted into the hospitals at Hyderabad, Scind, and Indore, Central India, we get a total of 3757 cases of stone in the bladder in patients of all ages and of both sexes. Amongst this number there were 94 females, 88 of whom were treated by litholapaxy, with a successful result in 87 cases. Brigade-Surgeon-Lieutenant-Colonel Forbes Keith treated all his female stone cases, 57 in number, by litholapaxy and lost only one patient. Surgeon-Lieutenant-Colonel Freyer treated 13 female patients out of a total of 17 by litholapaxy, and in no case did he perform a suprapubic lithotomy on a female. A glance at Table I. should convince the most sceptical that litholapaxy is capable of dealing most successfully with large stones in young girls and women, but judging from much that has been written about litholapaxy in boys I am quite prepared to see it gravely stated that litholapaxy should be adopted only in cases of small calculi occurring in girls, and that when the stone is of considerable size it should be removed by a suprapubic lithotomy. Such is certainly not my opinion. I think that in these days of aseptic surgery a vaginal lithotomy in an adult female will offer quite as good a chance of success as a suprapubic lithotomy. The clean incision made by a scalpel is readily stitched together, and if the vagina be rendered aseptic by filling it with iodoform gauze and a soft catheter be tied in the bladder perfect union should take place in four or five days. But the perfection of treatment for the vast majority of calculi in girls and women is unquestionably litholapaxy, and it is the ideal to which we should aspire if we are to obtain the maximum of success. For those who are being continually afforded opportunities of crushing stones in boys and men the operation of litholapaxy in girls and women is an extremely facile one. The route to the bladder in females is short and straight; there is no hypertrophied prostate to bar the way of the lithotrite into the bladder nor a post-prostatic pouch, that bugbear to successful litholapaxy in males, to be dealt with, and pouched bladders must be rare indeed in females. The instruments employed are the same as we use in boys and men, and as cases of stone are so rare in girls and women it would scarcely be worth while to fit oneself out with a supply of short evacuating cannulæ. I have always employed the same instruments in girls and women as I use in boys and men, and have found them in every way satisfactory. In some cases where girls and women strain very violently during the operation the bladder soon becomes empty of fluid, and then it will be a wise precaution to withdraw the lithotrite and inject some more water. Much aid will be given to the operator if his assistant presses the urethra against the lithotrite and cannula while they are being employed. The general surgeon in Europe is afforded but few opportunities of learning how to use a lithotrite with precision and with safety to his patient. This is his misfortune and not his fault. Bearing in mind the superiority of litholapaxy to all other methods of extracting a stone from the female bladder he will, I think, be acting wisely if he entrusts the few cases of calculi in females which he may meet with to one skilled in the use of the lithotrite.

TREATMENT OF

A CASE OF ADULT HYDROCEPHALUS BY SUPRA-TENTORIAL AND SUB-TENTORIAL OPERATIONS.

BY WILLIAM GORDON, M.A., M.D. CANTAB, M.R.C.P. LOND.,

PHYSICIAN TO THE DEVON AND EXETER HOSPITAL; PHYSICIAN TO THE WEST OF ENGLAND EYE INFIRMARY.

WHEN we recommend trephining for the relief of intracranial pressure it cannot be a matter of indifference whether the opening be above or below the tentorium, even when we do not aim at the removal of the cause. When the cause is situated below the tentorium this is especially obvious because the sub-tentorial space is so small compared to the general cranial cavity, its walls and roof are so unyielding, its outlets above and below so narrow, and a portion of its contents so vitally important and so sensitive to compression.

Adult internal hydrocephalus, apart from acute meningitis, is almost always due to sub-tentorial tumour, and is, indeed, a very common consequence of such a tumour. The tumour causes the hydrocephalus either (*a*) by compressing the veins of Galen; (*b*) compressing the outlet from the lateral ventricles; or (*c*) compressing both. There is a certain number of cases where, at the necropsy, the mechanism has seemed uncertain, but one of the above appears in most instances to be the correct explanation. From this it follows that in order permanently to remove the hydrocephalus in a case of tumour (at all events, in most instances) the tumour must (1) be removed, (2) subside, "be absorbed," or (3) become arrested at the same time that relief is afforded by some means to the compression already set up before arrest occurred.

1. *Removal.*—In the first case the opening would naturally be made below the tentorium. But such cases are few, because at present there are few sub-tentorial tumours which admit of removal. Some are undiscoverable from lack of exact localising data, and cerebellar tumours are very apt to belong to this class; some are inaccessible on account of their remoteness from the trephine hole; some are untouchable because either of their position amongst vital structures, their extent, their nature, their attachments, or their complications. The statistics show this. Dr. Hale White's series of 100 brain tumours[1] include 41 in which there was a sub-tentorial growth, 27 in the cerebellum, 2 in the cerebellum and pons, 6 in the pons, 1 in the pons and medulla, 1 in the medulla, and 4 growing from the dura mater. Of these 41 Dr. Hale White considered that 6 cerebellar tumours and 1 growing from the dura mater could probably have been removed. That is about 17·5 per cent., a percentage which seems to contrast very favourably with his estimate for the whole brain—viz., 10, or at most 14, per cent. There is, however, a further consideration on which Dr. Hale White lays emphasis. How many of these were discoverable? Cerebellar growths, which form the majority of those removeable, are apt to be latent or to give little more than so-called "general symptoms"—e.g., headache, vomiting, and optic neuritis. But the optic neuritis in cerebellar cases is remarkably constant,[2] more so, perhaps, than in tumours of any other part of the brain, usually early and often obtrusive, because loss of sight is often an early event. If, therefore, optic neuritis were absent I cannot but think that we should hesitate to trephine for the removal of a supposed cerebellar growth unless we had other very pronounced evidence of its existence. Now in 123 (81) of Dr. Hale White's series there was no optic neuritis, and therefore probably one would not have operated, although from the strictly pathological point of view it was to be regarded as removeable. Again in 36 (77) it is stated that the cerebral symptoms were masked by those of pyæmia, so that we can scarcely consider it. Omitting these two cases we have only 5 left which we can say were both diagnosable and removeable—i.e., 12·5 per cent. But how many of these

[2] Edmunds and Lawford: Transactions of the Ophthalmological Society, vol. iv., 1884, p. 172.

Hosted by Google

could have been so exactly localised as to be discovered at the operation? On this point the notes of the cases did not allow Dr. Hale White to come to any conclusion. Dr. Allen Starr[3] lays special stress on the difficulty of diagnosing cerebellar tumours unless they actually present at the posterior surface. Of 16 cases operated on in 9 the tumour was not found, in 2 it was found and could not be removed, and in 2 it was removed and the patient died. In 3 only—i.e., in 19 per cent.—was its removal a success. We cannot, of course, apply this percentage to the percentage deduced from post-mortem observation, but at least it suggests that the 12·5 per cent. of diagnosable and removeable tumours would be greatly reduced by the number which would be undiscoverable at the operation. We have, therefore, to consider what can be done in the great majority of cases when no removal can be hoped for.

2. *Subsidence.*—We may secure the subsidence of the tumour. Whether this ever applies to any tumour except a gumma is doubtful, but in any case subsidence requires time, and when symptoms are severe time cannot be afforded. Sudden death may intervene and is far from uncommon. It is, indeed, rather startling to note that out of 7 cases which Dr. Hale White considered removeable 3 died suddenly. Sight may be lost while we are waiting, and the combination of optic neuritis due to tumour and compression of the chiasma due to hydrocephalus is apt sometimes to act rapidly. Lastly, it is conceivable that the cortex may suffer from long-continued pressure. What can we do in the meantime? Two operations are open to us: we may trephine above the tentorium and tap or even drain the lateral ventricles (bearing in mind the two main risks of sepsis and over-quick escape of fluid) or we may trephine below the tentorium and allow the sub-arachnoid space to empty itself. All we want is temporary relief and either may afford it.

3. *Arrest.*—But few cerebellar tumours are syphilitic, and cerebellar tumours form the majority of sub-tentorial tumours, therefore presumably this majority will not subside under iodide and mercury or otherwise. We can then only hope for arrest, and fortunately arrest is not very rare, especially in the case of tuberculous masses. But we must manage more than a mere arrest of the growth, for there is pressure already set up and we have to relieve it, and relieve it permanently. For this purpose a supra-tentorial opening will not do, since tapping the lateral ventricles is plainly out of place, and permanent drainage is too dangerous to be thought of. But another possibility presents itself. May not an opening made below the tentorium effect what we require? It will certainly relieve the general sub-tentorial pressure and even when skin and muscle are closed over it it will continue to give additional space. By thus relieving the general pressure, may we not fairly expect it also to relieve the local pressure on the veins of Galen or the outlet from the lateral ventricles? If so, the cause of the hydrocephalus should disappear and the hydrocephalus disappear with it. In the following case the conclusion that something of this sort has occurred can scarcely be escaped.

The patient, a rather strumous-looking girl aged seventeen years, was admitted to the Devon and Exeter Hospital on Dec. 28th, 1894, with complete blindness, well-marked double optic neuritis, headache, and a history of vomiting. She was not anæmic, had no symptom of plumbism, and her urine was normal. She gave the following history, which her mother confirmed. Up to the preceding March she had been perfectly well, but about that time she noticed that when out walking in the dusk a dark shadow would suddenly come over her sight, and "for one or two minutes" she could not see. At first this was very occasional, but gradually it became more frequent, occurring several times in the same evening, and the loss of sight became longer, "three or four minutes at a time." Later (she was very indefinite about her dates) this began to occur in the daytime as well, and soon looking at any bright light would take away her sight for several minutes. In the intervals vision was becoming progressively worse. She had always been subject to "bilious attacks" of headache and vomiting, but since March these had become more frequent—about once a fortnight, usually in the morning, and accompanied by vertigo. On Nov. 5th, 1894, she went to the West of England Eye Infirmary, being then almost blind. Pronounced double optic neuritis was found and the following note was made: "Vision of the right eye, shadows; of the left, $\frac{1}{60}$. She has had for the past week shaking attacks all down the right side, occasionally only the arm being affected. These attacks came on on alternate days and she was sick the whole day. The attacks did not begin in any particular spot and she did not lose consciousness. There is constant headache, most acute over the left ear; no tenderness of head discoverable, no paralysis of motion or sensation." She was put on a mixture of bromide and iodide of potash, and for a time the headache and sickness disappeared, nor were there any more "shaking" attacks. On Christmas night she was awakened by intense headache all over her head, with violent vomiting and "shaking" all over, with great tenderness of the skull. She was admitted to the Devon and Exeter Hospital on the 28th. As regards past illnesses, she had had none lately. She had had scarlet fever as a child, but it left no sequelæ. She had never had a blow on the head or any discharge from, or pain in, either ear and had never been deaf. Her father and mother were both alive and well, aged forty-six and forty-four years respectively. A brother and sister (twins) died in infancy from convulsions. Her mother's sister died from what appears to have been phthisis. There was no evidence of syphilis. The patient was a fairly-nourished but somewhat strumous-looking girl with a drowsy expression. She was absolutely blind and could not tell where the windows were. Her speech was clear but deliberate; her answers were quite intelligent but delayed, and then commencing rather suddenly in an unnecessarily loud tone. Her memory seemed to be unaffected. She walked easily and well when guided. There was slight headache on the left side of the head between the ear and the occiput; there were no sickness and no giddiness and the patient slept and ate well. She was given thirty grains of iodide three times a day with small doses of mercury. There was a very slight tremor of the right arm, which movement did not increase. No paralysis of motion or sensation was present. The right knee-jerk was greatly diminished, the left being normal. The condition of the cranial nerves was as follows: 1. There was complete bilateral anosmia (practically no coryza was produced by the iodide). 2. Absolute blindness existed for the last week. 3, 4, and 6. The pupils were equal, but sluggish in reacting to light. No strabismus or nystagmus was present, but both lateral conjugate movements of the eyes seemed feeble. 8. Normal. 5, 7, 9, 10, 11, and 12. Normal. The heart, lungs, and abdomen were natural and the temperature was normal. The optic neuritis was very intense and the swollen papillæ were rather pale. The diagnosis was intra-cranial tumour. The early blindness, occipital headache, early and sometimes severe vomiting and vertigo, with absence of motor or sensory paralysis (anosmia and sluggish lateral movements of the eyes excepted), favoured the suggestion that it was cerebellar. The "shaking attacks" in the arm and the persistent slight tremor in it, taken with the sluggish ocular movements, might have raised a suspicion of its being pontine, but pressure on the pons from above might, it was thought, explain these. The drowsiness, slow speech, and delayed answers, with the early blindness, were regarded as suggesting distension of the lateral ventricles. Putting everything together it was considered that the tumour was certainly sub-tentorial and probably in the fore and under part of the cerebellum. As iodide and mercury were evidently useless and it was possible that operation might in some measure restore the sight and relieve the headache it was decided to trephine. It did not then occur to me that trephining could prove to be more than a palliative measure and therefore the position of the opening seemed immaterial.

Operation 1. Supra-tentorial.—Accordingly, on Jan. 1st, 1895, my colleague, Mr. Bankart, trephined. The centre of an inch trephine was placed on a line drawn vertically from the external auditory meatus at a point about four and a half inches above the external meatus and three inches from the antero-posterior mid-line of the skull. The dura mater bulged and scarcely any, if any, pulsation could be perceived, and on incising it the brain bulged out so forcibly that to prevent an immediate and considerable hernia it was necessary to push a small trocar and cannula into the ventricle. About six drachms of clear, slightly albuminous fluid were drawn off. The brain bulged less and pulsation could be seen in it. The flaps were replaced and sutured. The patient rallied well and the wound did admirably. On the 3rd some slight amnesia was noticed, and this was more marked next day, when some slight weakness was observed in the right side of the mouth and the right side

[3] Starr: Brain Surgery, p. 216.

Hosted by Google

of the tongue. These symptoms were considered to be due to the position of the opening and soon disappeared, so that on the 7th they were noted to be gone. The temperature had remained normal since the operation and the headache had completely left her. There was also no further vomiting or vertigo. The sight, however, had not returned and did not do so subsequently. Other symptoms now began to make their appearance. The speech became blurred and sibilant as if she was speaking with her mouth full of saliva; slight divergent squint was observed, apparently from weakness of the internal recti, and there was some nystagmus on looking towards the right. On the 8th there was slight proptosis, more marked on the right side, and slight nystagmus on looking either right or left. She was drowsy, with a furred tongue and offensive breath. There was defective sensation to touch over the lower part of the face on the right side, complete loss of sense of touch all over the right arm (the sense of pain was retained), and allochiria over the left arm; on the legs and trunk there was patchy anæsthesia. The right leg felt "sleepy and tingling." On the 9th some weakness was noticed in the right hand, and next day the right hand became absolutely palsied. Both knee-jerks were completely lost. There was no weakness of either leg. On the 11th the hand began to recover power, but there was slight ptosis noted on the left side. On the 14th, although there was no weakness of legs, she could not stand on attempting to do so (for the first time since the operation), as there was marked incoördination, the legs being thrown wildly about. On the 17th the left pupil was noticed to be larger than the right, the right reacted slightly to light, but the left not at all. The relative size of the pupils after this date was somewhat variable, but when unequal the left was always the larger. On the 20th the hernia cerebri, which had been steadily increasing, had become so large that it was feared the skin over it might give way, and therefore an exploring needle was pushed through it into the ventricle and eleven drachms of fluid drawn off. On the 26th the patient was very drowsy and said her right leg felt sleepy and tingling again. Next day she complained of severe pain in the right side of the abdomen, which was extremely hyperæsthetic. Her temperature rose to 103·2° F. with a slight rigor, and the right arm and leg became flaccid and powerless. With this the right knee-jerk, which, like the left, had been completely abolished, returned and became excessive with ankle clonus, the left knee-jerk remaining absent. On the 30th she was very irritable and lay curled up on her right side. There was some occasional retraction of both sides of the mouth. On Feb. 3rd she was almost unconscious, scarcely recognised her mother's voice, and passed her motions under her. The temperature had again become normal. From this date she improved, the hyperæsthesia and irritability passing off and some return of power showing itself in the arm and leg (not in the hand). But the hernia was again increasing and drowsiness became very marked. At last, on Feb. 12th, this almost amounted to unconsciousness; she evinced no interest in her surroundings and seemed steadily passing into coma. So serious did her condition appear that it was thought admissible to run the risk of draining the ventricle and a small hydrocele trocar and cannula were again passed in through the hernia. Before withdrawing the cannula a very small (No. 1) catheter was pushed in and afterwards tied in place, large dressings being applied over it. A great quantity of fluid drained away, the catheter being kept in for three days. The effect of this drainage was unmistakeable. Improvement at once set in, and on Feb. 18th a note was made that "she is much better, lies straight in bed, and is bright and cheerful." Her movements became brisk again and the drowsiness vanished. After the catheter was removed the drainage did not cease, but merely lessened, the fluid continuing to escape apparently along the track the catheter had left. On Feb. 25th the "hernia less tense, greatly better." The drainage now ceased, and with its cessation drowsiness began to return, so that on Feb. 28th "she is very drowsy again; no drainage." On March 1st free drainage through the hernia re-commenced spontaneously and went on intermittently for a fortnight, one or two days at a time with intervals of two or three days. With this the drowsiness again disappeared and remained absent, and she began to regain the flesh which she had lost. On March 11th it was noted that there was some weakness of the conjugate lateral movement of both eyes towards the right. Then came a week during which there was no drainage and drowsiness again became very marked. It now occurred to me that a sub-tentorial opening might have the effect referred to above, and accordingly on March 21st (Mr. Bankart being away) my colleague Mr. Harris operated.

Operation 2. Sub-tentorial.—After raising the soft parts a three-quarter inch trephine-hole was made over the left cerebellar hemisphere which bulged considerably. It was thought possible that the tumour might be cystic, and so a small trocar was passed in two directions forwards, inwards and upwards, but no fluid was found. The flap was replaced and sutured; the patient rallied well and the wound did excellently. Without giving detailed notes it will be sufficient to say that since this second operation there has never been the slightest return of drowsiness. An attack of headache and vomiting occurred about four months ago which rapidly subsided under iodide and mercury, but no drowsiness accompanied it.

On Dec. 14th I saw the girl at her home. She was perfectly intelligent, cheerful, and happy; she showed no trace of drowsiness, her answers were not delayed, and she only occasionally hesitated for a word. There had been no return of drainage through the hernia, and the hernia was greatly reduced in size and quite flaccid. This reduction was no doubt largely owing to a gentle continuous pressure applied by Mr. Harris. There was a considerable but soft bulging over the sub-tentorial trephine-hole. Smell was absent, but taste was present (said to be variable). Sight remained absent and the discs were white and filled in, but without much change in the calibre of the vessels. The conjugate movement of both eyes was to the left (it used to be to the right), was weak, and there was some nystagmus in all directions. The pupils were large and equal, reacting slightly to light. There was no proptosis. Sensation to touch was normal on the face. There was very slight weakness of the right side of the mouth and the tongue deviated slightly to the light. Her right hand was powerless, but she could move the arm fairly. Both legs were very weak and she could not stand, but there did not seem to be much difference between them except that flexion of the ankle was weaker on the right than on the left. Sensation was lost on the right leg from the foot to slightly above the knee and on the right hand and half way up the forearm. The plantar reflexes were normal, the left knee-jerk was lost, and the right exaggerated, and there was ankle clonus on the right side. The sphincters were normal. She had no pain of any kind and no sickness, had an abnormally good appetite, and had decidedly gained flesh. The growth seems to have been arrested. Whether the arrest is permanent remains to be seen. If it was, as I was inclined to think, tuberculous tubercle might show itself sooner or later in the lungs. She had an occasional slight dry cough, but no physical signs in the chest.

I have given the case practically in full, and it will be obvious that the position of the first trephining by its effects greatly confused the symptoms; but the following points seem clear, and it is to these I wish to draw attention: (1) the case was clearly one of intra-cranial tumour; (2) it was also clearly, I consider, one of sub-tentorial tumour; (3) internal hydrocephalus was marked and increasing; (4) a supra-tentorial trephining was a means of gaining time; and (5) a sub-tentorial trephining appeared to remove the hydrocephalus permanently. I am glad of this opportunity of expressing my great indebtedness to my colleagues, Mr. Bankart and Mr. Harris, for so kindly undertaking the surgery of the case, and also to the house surgeon, Mr. Andrew, for the skill and care he bestowed on the after treatment.

Exeter.

THE GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN.—This hospital, designed by Messrs. Roumieu and Aitchison, honorary architects, now being erected at the south corner of Vincent-square, Westminster (the foundation stone of which was laid by Lady Kortright in July last, who has been a munificent donor to the building fund), is to be constructed upon the latest lines of efficiency. The materials are red brick and red terra-cotta, the style of architecture aimed at being that of Free North Italian Gothic. It is expected that the Princess Louise will open the hospital next season. The cost of the building is nearly £9000, exclusive of the out-patients' department lately erected at a cost of £3000.

ON RE-DUPLICATION OF THE SECOND SOUND.

BY ARTHUR G. PHEAR, M.D. CANTAB., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL.

THE closure of the semilunar valves is associated with a sound which under ordinary conditions is single. Under special circumstances the sound becomes divided into two parts and is described as re-duplicated. The term "re-duplication of the second sound" has, however, been extended to denote a phenomenon which is quite distinct from doubling of the second sound proper and which consists of the interpolation of an extra sound of doubtful mechanism following the second sound, which thus may seem to be doubled. Owing to this extension in its use, some ambiguity has arisen in regard to the significance of the term, an ambiguity which may best be avoided by employing it only in its strict meaning—i.e., when an actual doubling of the second sound exists. It is a matter of importance to differentiate the genuine from the spurious forms of re-duplication, and in the course of this communication an attempt will be made to indicate briefly how this distinction can be drawn. In the event of the second sound appearing to be doubled the following points should be ascertained: (1) The area over which the double sound is audible as such, and of this area the special point at which the double nature of the sound is most distinct; (2) the rhythm of the double sound, whether one part follows the other in the closest proximity, or leisurely after an appreciable interval; and (3) the quality of the two sounds, whether they are alike (each one resembling the normal second sound), or one only with the special character of the second sound, the other notably differing.

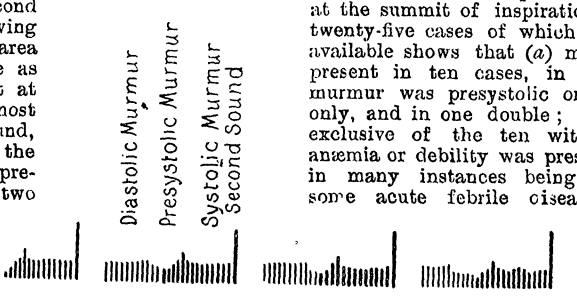

FIG. 1.

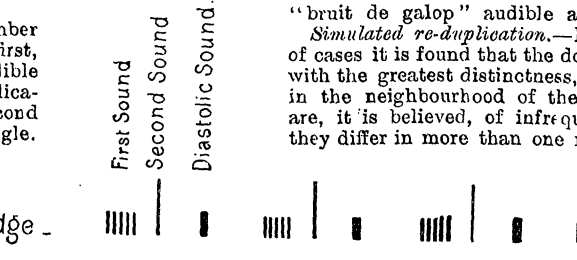

Genuine re-duplication.—In a large number of cases such an investigation shows, first, that the doubled sound is most clearly audible at the base. In many instances the re-duplication is limited to this region, the second sound at the apex, if audible, being single. In other cases, but less commonly, a double sound is heard at both apex and base, but with much more distinctness at the base than at the apex. Secondly, the two elements of the double sound are in close proximity, the interval by which they are separated being exceedingly short. Thirdly, the two elements, although they may differ in loudness, in other respects are similar, both possessing the special qualities by which the normal second sound is characterised. Re-duplication which conforms to the above description in every respect of distribution, rhythm, and quality is of frequent occurrence, and it is difficult to regard such cases in any other way than as examples of true doubling of the second sound, in all probability produced by the asynchronous closure of the pulmonary and aortic valves. The clearness with which the double sound is heard at a spot where presumably both aortic and pulmonary elements share in the composition of the second sound is in accordance with this view, which is further favoured by the similarity of the two parts of the double sound, and by the shortness of the interval by which they are separated. The re-duplication is often still more limited than has been indicated; it is frequently audible only to the left of the sternum, the second sound as heard to the right of this bone being single, or only indistinctly doubled. From this it would appear, as has been pointed out elsewhere,[1] that the pulmonary element of the second sound is singularly circumscribed in its conduction, as compared with the sound of aortic origin.

The circumstances under which a genuine re-duplication of the second sound may be produced are numerous. It appears to depend on a disturbance of the relation which normally exists beween the pulmonary and aortic pressures. High pulmonary tension is often accompanied by re-duplication, which is thus a common feature of mitral stenosis, mitral regurgitation, and other conditions in which the flow of blood through the lungs is hindered. It may be met with in cases of anæmia and debility; and in these, as also in cases of mitral disease, there is present in addition to the re-duplication, an accentuation of the second sound as heard to the left of the sternum. Re-duplication is by no means so commonly associated with high systemic pressure; it is occasionally heard, however, in cases of chronic interstitial nephritis, with hypertropied and strongly acting left ventricle. In many healthy persons it is produced when a deep breath is taken and held at the summit of inspiration. An analysis of twenty-five cases of which detailed notes are available shows that (*a*) mitral murmurs were present in ten cases, in five of which the murmur was presystolic only, in four systolic only, and in one double; (*b*) in twelve cases, exclusive of the ten with mitral murmurs, anæmia or debility was present, the individuals in many instances being convalescent from some acute febrile disease; (*c*) two were cases of acute lobar pneumonia; and (*d*) in one case there was hypertrophy of the heart, with high-tension pulse and "bruit de galop" audible at the apex.

FIG. 2.

Simulated re-duplication.—In a certain number of cases it is found that the double sound is heard with the greatest distinctness, not at the base, but in the neighbourhood of the apex. These cases are, it is believed, of infrequent occurrence and they differ in more than one respect from the re-duplicated second sound just now described. If the stethoscope be placed at the second left intercostal space, close to the sternal edge, a single second sound is heard. As the stethoscope is shifted downwards in the direction of the apex another sound becomes added to the normal second sound, occurring subsequently to it and after a definite interval. The quality of this interpolated sound varies; it is usually short and abrupt, but can be clearly distinguished in some respect of pitch or timbre from the second sound which precedes it. It is limited in distribution, being distinctly audible only in the neighbourhood of the apex-beat—as a rule between this point and the left border of the

[1] The Clinical Significance of Accentuated Second Sound By Ringer and Phear. THE LANCET, Sept. 29th, 1894.

Hosted by Google

sternum, in the fifth or fourth interspace. Whatever be the mechanism by which such a double sound is produced, it can hardly be attributed to the asynchronous closure of the pulmonary and aortic semilunar valves; its area of audibility, the length of the interval which separates the two elements, and the dissimilarity of these elements are all opposed to such a view. The phenomenon cannot be regarded as a true re-duplication of the second sound; it differs, in its clinical features so widely from this that it can hardly be described as simulating genuine re-duplication very closely. By its position in the earlier part of diastole the abnormal sound may readily be distinguished from that which constitutes the "bruit de galop," and which in cases of interstitial nephritis with hypertrophied heart may give rise to an apparent doubling of the first sound. The rhythm indeed produced by the sequence of first sound, second sound, and early diastolic sound resembles more closely that of a canter than of a galop. It has been compared with a dactyl – ∪ ∪; but it may be more accurately indicated in musical notation, thus, a crotchet, two quavers, and a crotchet rest, the crotchet representing the first sound, the two quavers the second and interpolated sounds, and the crotchet rest standing for the pause before the cycle recommences. The two following cases are of interest in connexion with this subject.

CASE 1.—The patient was a man aged thirty-six years, who gave no history of rheumatism, but in the course of his life had been subjected to severe strain. He was very anæmic. The pulse was 80, small, and compressible, but regular. The apex beat was located in the fifth interspace in the nipple line. The impulse was weak; no thrill was felt. With the stethoscope a systolic murmur was heard at the apex, followed by the second sound; these two were constant. In addition two further signs were frequently audible, a presystolic murmur preceding and running up to the systolic murmur, and a short valvular sound in diastole, of a quality quite distinct from that of the second sound and dividing the interval between the second sound and the presystolic murmur into two approximately equal parts. On taking note of the relation of the respiratory movements to the presystolic murmur and the diastolic sound it was found that the murmur and sound were produced only during the later part of inspiration and the earlier part of expiration; they were thus heard in two or three beats of every five. These facts may be rendered clearer by a diagram. (See Fig. 1.) The diastolic sound was audible at the apex and between this point and the sternal margin in the fourth and fifth interspaces, but no higher than the fourth interspace. Although with none of the qualities of murmur it was not so sharp and clearly defined as the second sound which preceded it.

CASE 2.—This patient was a man aged fifty years. There was a history of more than one attack of rheumatic fever. The pulse was 40, regular, of slow rise, long duration, and gradual fall. The apex beat was in the fifth space, immediately to the left of the nipple line; the impulse was localised and heaving. A thrill, of presystolic rhythm, was felt in the region of the apex, at times continued into the early part of systole. Over the same area there was heard a presystolic murmur, running up to a long soft systolic murmur, which was terminated by the second sound; this was followed by a pause, but of short duration only, since the greater part of diastole was occupied by a long drawn-out murmur continuous with the rough presystolic reinforcement alluded to above. The auscultatory signs were specially easy to study by reason of the infrequency of the heart-beat. On shifting the stethoscope along the fifth interspace as far as the sternal margin the signs were materially altered. No murmur was audible at this spot. The first and second sounds were heard and, following these in the first half of diastole, a sound of short abrupt quality, not a murmur, yet quite unlike the second sound. (See Fig. 2.) The abnormal diastolic sound was plainly audible in both fifth and fourth interspaces close to the sternal edge, less distinctly in the third, and very indistinctly in the second interspace, where it was preceded by a loud accentuated second sound, very much louder than over the fifth interspace.

An interpolated sound similar to that which forms the chief point of interest in the above cases has been noticed by several observers, most of whom insist on its connexion with mitral stenosis. It is probably that described by Bouillaud[2] as the "bruit de rappel"; he compared it in rhythm to "the noise of the hammer which, after striking the iron, falls on the anvil, rebounds, and falls again motionless." Sansom drew attention to the sign in association with mitral narrowing in 1880,[3] and more recently[4] he has stated that it is to be found in at least one of every three cases of mitral stenosis; he regards it as especially a sign of the earlier periods of the history of the disease. It is also described by Potain[5] under the name of "claquement d'ouverture" of the mitral valve; he believed it to be evidence of a somewhat advanced degree of mitral stenosis, but short of great rigidity of the mitral valve.

It is not intended to discuss the mechanism of this abnormal sound. An endeavour has been made to indicate the features by which it may be distinguished from a true re-duplication of the second sound, and it is urged that, by whatever name it be designated, one be chosen which is descriptive of the phenomenon and may serve for its clinical recognition, without involving any unproved theory as to its mode of production, concerning which our knowledge is at present so deficient.

NOTE ON THE SMEGMA BACILLUS: ITS DIAGNOSTIC IMPORTANCE AND ITS CULTIVATION.

BY ALBERT S. GRÜNBAUM, M.A., M.B. CANTAB, M.R.C.P. LOND.

(FROM THE CLINIC NOTHNAGEL, VIENNA, JUNE, 1896).

THE smegma bacillus was discovered in 1885 by Matterstock,[6] and by Alvarez and Tavel,[7] independently. During the succeeding three years a large number of papers was written on the relations of the bacilli of smegma, of syphilis, and of tubercle, but since then the subject has been comparatively neglected. Although even at that time some writers indicated the possibility of its occurrence in the urine, and of its being mistaken for the tubercle bacillus, a possibility emphasised by Lustgarten and Mannaberg[8] when they found the smegma bacillus to be a normal inhabitant of the male urethra, the question does not seem to have been systematically examined[9] or thoroughly appreciated by most text-books on clinical diagnosis or on the examination of the urine, especially in this country. That the smegma bacillus frequently occurs in the urine, especially of females, had been known for some time in the Clinic Nothnagel when, at Dr. Mannaberg's suggestion, I undertook to determine the actual frequency and attempt the cultivation of the bacillus. Whilst my work was in progress a discussion in the Berlin Verein für Innere Medicin[10] showed that, although many clinical observers were aware of the facts, they considered them insufficiently well known, so that I have the less hesitation in partially repeating the observations there made.

Fifty specimens of urine from forty-seven individuals affected with various diseases (some with cystitis) were examined, ten from males and forty from females. The specimen was centrifugalised, the deposit spread on a cover-glass and stained in the usual way for tubercle bacilli with the Ziehl-Neelsen and Gabbett solutions. No smegma bacilli were found in any of the specimens obtained from males, but they have occasionally been found by other observers. Of the other specimens eleven were obtained by catheter; in none of these were any bacilli found. In the remaining twenty-nine specimens obtained in the ordinary way bacilli were found in seventeen; in the remaining twelve none were detected.

In the above numbers are included eight specimens obtained in the following way. A portion of urine was first

Hosted by Google

passed in the normal manner and the remainder then withdrawn by catheter. In the case of two patients no smegma bacilli were found in either portion; in that of the other two the urine passed in the normal manner contained them, whilst the portions obtained by catheter did not.

From these numbers it would appear that the smegma bacillus is to be found but rarely in the urine of males (in spite of its presence in the urethra) and in about 59 per cent. of females (in whose urethra I was unable to demonstrate the presence of the bacillus in six specimens examined). This percentage is probably rather too low, since some of the urines, by the kindness of Professor Schauta and his assistant Dr. Wertheim, were obtained from the gynæcological out-patient room, where patients have usually washed the external genitals before presenting themselves for examination.

In tabular form the results are as follows:—

	Normal.		Catheter.	
	Found.	Not found.	Found.	Not found.
Males	—	10	—	—
Females	15	10	—	7
(Separate portions from four patients)	2	2	—	4

For purposes of diagnosis various colouring methods have been proposed and recommended by various observers, most recently of all by Grethe,[11] who recommends the use of alcoholic methylene-blue solution for decolourisation instead of an acid solution. It appears to me that erroneous results are obtained by considering the colour-capacity of the smegma bacilli to be the same whether in smegma or in urine, since they are much more easily decolourised in the latter; and also that it is unpractical to now recommend a new method for staining tubercle bacilli when, in England, at any rate, the Ziehl-Neelsen and Gabbett solutions are in almost general use. As a matter of fact, one minute's immersion in absolute alcohol is sufficient to decolourise the smegma bacilli in urine, but, *as a rule, careful catheterisation eliminates all sources of diagnostic error*. This had been previously shown by Lustgarten and Mannaberg to hold good for the male, and the above results indicate that it applies equally for the female. It is therefore unnecessary, except to localise disease when present, to catheterise the ureters as was done in the case upon which the discussion in the Berlin Society arose. On that occasion Leyden stated that the smegma bacillus could be found in nearly every urine and that it never showed the irregularities of the tubercle bacillus. I was not fortunate, or, perhaps, not industrious enough to confirm the first statement by very thoroughly examining two cover-glass specimens in each case where no bacilli were found. The second statement is certainly not absolutely correct, for irregular specimens of the smegma bacillus exactly resembling the tubercle bacillus are to be found. As a rule, however, the former have a regular contour and more angular extremities than the latter, and, as has been frequently pointed out, occur in small groups or on shed epithelial cells. So that, all points taken into consideration—viz., their shape and grouping, their easy decolourisation by alcohol, and, principally, their absence in the urine obtained by catheter—the distinction does not present insuperable difficulties.

So far as I am aware no bacillus which gives the colour reactions of the tubercle bacillus has hitherto been cultivated from smegma. After trying many culture media I succeeded in growing in milk (but not in obtaining a pure culture) a bacillus which stained red with carbol-fuchsin, and was not decolourised in two minutes by Gabbett's solution. Although it may be that the fat in the culture medium assists the growth and composition I do not think that it causes the colour reaction, as suggested for other bacilli by Bienstock[12] and Gottstein,[13] because the other cocci and bacilli (one of which, a short, slender bacillus, easily isolated on gelatin, causing coagulation of milk, and constantly present) do not retain the red stain. Some effect may be due to the culture medium, since a bacillus, resembling that of smegma, which grows on agar serum, gives the colour reaction partially. This side issue is the more interesting since latterly tubercle bacilli (dried) have been found to contain 37 per cent. fat. In milk the bacillus assumes the short, rather plump form found in the smegma of the male, as compared with the rather more slender form found generally in the smegma of the female. Unfortunately, cultivation cannot be used for diagnostic purposes, since it will not grow from every urine in which it is present.

CEREBELLAR ABSCESS FOLLOWING MASTOID DISEASE; DEATH; NECROPSY.

BY J. BROOKE RIDLEY, M.D. EDIN.,
LATE HOUSE SURGEON, HUNTS COUNTY HOSPITAL; AND LATE ASSISTANT MEDICAL OFFICER, METROPOLITAN ASYLUM FOR CHILDREN, DARENTH.

INTRA-CRANIAL lesions the result of ear disease are of such marked interest owing to the important progress surgery has made in this direction, more especially with regard to cerebellar abscess, that any additional case in which this lesion has existed must necessarily be of considerable interest, for, so far as I am aware, the recorded cases are not numerous.

A schoolboy, fourteen years of age, had suffered from a discharge from the right ear for seven years, the result of acute otitis media during an attack of measles. About four years previously to his being seen by me the discharge ceased; he then had severe earache for some days, which got well without any treatment; beyond this he had had no trouble till the present attack, which started with the usual history given—cold, then cessation of the discharge. He had been confined to bed for a week suffering from severe earache together with the invariable concomitant symptoms which generally attend sudden stoppage of a discharge in this region, whether set up by a catarrh, polypus, granulations, or inspissated pus. As he was daily getting worse I saw him first on Jan. 7th, 1896. He looked very ill and was evidently in great pain; the face had a worn and anxious expression; the temperature was 105° F., and the pulse 125; the tongue was covered with a thick brown fur, the breath being most offensive; there was a cough, with bronchial catarrh of both lungs. He complained of acute pain in the mastoid region, radiating down the neck and towards the frontal, parietal, and occipital regions, severe headache, anorexia, retching, and insomnia, with a certain amount of delirium at night. There was marked tenderness over the jugular vessels; no redness or œdema over the mastoid presented, but slight pressure caused intense agony. Otoscopic examination of the right ear showed the external meatus free, with flakes of green pus adhering to the walls, the membrana with the malleus and incus were absent, and the tympanic cavity was clear and not inflamed. The left ear was normal. There was no photophobia, optic neuritis, or paralysis of any nerves present. He was quite conscious. To save reiteration I may here state that at no time was there any evidence of photophobia, optic neuritis, inequality or sluggish action of the pupils, or paralysis of any cranial nerves present, although repeated and careful examination was made upon numerous occasions throughout the illness. The diagnosis was acute inflammatory suppuration of the mastoid cells due to blocking of the exit from the antral cavity and possibly starting sinus thrombosis. The extreme gravity of the case and danger to life, with the benefits to be gained by the recognised surgical procedure of the day, were laid before the parents, but they refused to give consent to any operation, seeing that he had got well in the former attack without such being necessary. This being the case the line of treatment adopted was of a palliative nature and such as would relieve the most urgent symptoms—a calomel purge, quinine, and spongio-piline as hot as could be borne applied to the mastoid region hourly. Needless to say, there was no change in his condition during the first twenty-four hours. The meatus was well syringed out daily with warm antiseptic lotion. In the course of the next few days a sub-periosteal abscess appeared at the back of the right ear and above the level of the meatus. Much against the parents' wish this was opened by a free incision down to the bone, giving exit to a quantity of foul-smelling green pus. Bare and roughened

Hosted by Google

bone was felt. A probe could be passed along a sinus into the antral cavity, whilst a steel director was easily pushed through the necrosed portion into the mastoid cells, giving free exit to more pus. The beneficial effect of this was kept up by linseed-meal poultices. The temperature fell to 100° and the pain abated. On Jan. 12th rigors began, followed by profuse sweating, copious diarrhœa, and vomiting. He looked very anæmic; the temperature was irregular; he was obviously much worse and in a condition of danger. These symptoms pointed strongly to, and were highly suggestive of, a pyæmic involvement of the system or that of abscess formation. The rigors varied from three to six a day and the temperature from 99° to 105°. The mother stated that she had noticed twitching on the right side of the face, but this I was never able to verify for myself. On Jan. 19th the wound behind the ear was closing up, but still discharged pus. The pain in the head was gone. He did not complain when firm pressure was made over the mastoid, digastric fossa, or jugular vessels, but he was restless, with irritability of temper and fits of depression. On Jan. 26th the vomiting, which had been of daily occurrence, was more marked and occurred several times a day. The diarrhœa ceased; the tongue was quite clean; there was a certain amount of emaciation present; the temperature was subnormal; there were no rigors; there was retraction of the abdominal walls and *tache cérébrale* was well marked. The pulse and respiration were slow. Cerebration was sluggish, the patient taking a long time to answer a question. Upon percussing the head no pain was complained of beyond that of a well-defined area over the right occipital region; here slight tapping caused great pain. On making him walk staggering gait was quite apparent, and on the patient closing his eyes there was a tendency to fall forwards; this together with the other symptoms was evidence in favour of cerebellar abscess. On Feb. 1st the incision behind the ear had quite healed; he sat up in bed, played with toys, and amused himself drawing pictures. Vomiting was still marked. The pulse was 40, the temperature sub-normal, and respiration slow but regular. There was no change in his condition till Feb. 7th, when he did not take so much notice of things and seemed difficult to rouse. He lay on his left side huddled up in bed, with the legs and thighs flexed. Constipation was present. The pulse, temperature, and respiration were as before; the vomiting was more frequent. On Feb. 12th violent paroxysms of acute pain set in over the vertex of the skull, causing him to clasp his hands over his head and scream during the attacks. Purgation and opium diminished their intensity and frequency. It was quite evident the end was slowly approaching. He was getting very emaciated. There was never any retraction of the head or Cheyne-Stokes respiration. On Feb. 22nd he sat up in bed to ask for a drink and fell back dead. The vomiting never abated and the temperature remained subnormal. After great difficulty permission was granted for a post-mortem examination of the head only.

Necropsy.—The skull cap came away easily; the dura mater was not adherent in any part; a degree of fulness was apparent as though there were increased intra-cerebral pressure; the dura mater stripped off easily, and with the exception of the veins being somewhat distended the surface of the brain looked healthy. There was no sign of meningitis, no caries of the petrous bone, a slight increase in the amount of cerebro-spinal fluid at the base, but no meningitis. The right tentorium cerebelli was seen to be distinctly bulged. On dividing it a large abscess was to be seen occupying the anterior and outer portion of the right lobe of the cerebellum evidently on the verge of bursting. The membranes were not adherent, neither was there any healthy layer of brain tissue seen to be intervening. On attempting to remove the brain the abscess burst and a quantity of offensive green pus escaped. There was a distinct limiting membrane encapsuling the abscess from the neighbouring brain tissue, but no channel of communication with the mastoid cells was to be found. There was no localised abscess beneath the dura mater covering the bone in this region; in fact, the membrane came away easily in the posterior fossa, leaving to all appearance a healthy surface. There was no thrombosis of the lateral sinus. The pons and medulla, with the remainder of the cerebellum, were healthy. On cutting into the brain the lateral ventricles were markedly distended and filled with clear fluid. Beyond this no other lesion was to be found. The mastoid cells and antrum were found to be free from pus; the incision wound was quite healed.

St. John's, Woking.

REMOVAL OF A
RAPIDLY GROWING OVARIAN CYST WHICH HAD BURROWED BETWEEN THE UTERUS AND THE BLADDER

IN A PATIENT WHO HAD BEEN RECENTLY CONFINED, AND ON WHOM OVARIOTOMY HAD BEEN PERFORMED EIGHTEEN MONTHS PREVIOUSLY.

BY A. C. BUTLER-SMYTHE, F.R.C.S EDIN.,
SURGEON TO THE GROSVENOR HOSPITAL FOR WOMEN AND CHILDREN, AND SURGEON TO OUT-PATIENTS AT THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.

A MARRIED woman aged twenty-four years consulted Dr. Seccombe of Terrington, Norfolk, in March, 1892, on account of pains in her stomach which were at first thought to be due to flatulence. On examination a tumour was discovered which was diagnosed, in consultation with Dr. Plowright of King's Lynn, to be an ovarian cyst. The patient was sent to the Samaritan Free Hospital and was admitted under my care on April 30th, 1892. The following history was elicited from her. Menstruation first appeared at twelve years of age, and since then the periods had been regular though scanty. She had been married two and a half years, but had not become pregnant. In June, 1891, she had influenza, and in the following August very nearly succumbed to an attack of measles which left her in a delicate state of health. Her first experience of abdominal pain occurred in February, 1892, and as it became worse she sought medical advice. On admission the patient, who was much emaciated, flushed, and feverish, complained of great tenderness in her abdomen and was evidently suffering from extreme distension, the circumference at the umbilicus being forty-eight inches. Her breathing was rapid and shallow, the pulse was 120, and the temperature was 101° F. The tongue was coated; the urine was acid, of specific gravity 1015, clear, and contained no trace of albumin. The abdomen was œdematous and the vulva and thighs were swollen. Her appetite was fair, but she had been losing flesh steadily for the last few months. Of late she could not lie on her right side because of a dragging pain in her abdomen to the left of the umbilicus. The abdomen was distended by a tense swelling which fluctuated freely. There was dulness up to the ensiform cartilage and in both flanks. The tumour was adherent to the parietes. Per vaginam the uterus was found to be behind the tumour, which almost filled the pelvis. The uterine cavity measured two and a half inches and the uterus could be moved laterally. On May 4th Mr. Stormont Murray administered ether, and assisted by my colleague Dr. Rutherfoord (Dr. Seccombe and other visitors and colleagues being present) I opened the patient's abdomen, separated the parietal adhesions and tapped the tumour, thirty-four pints of dark, viscid fluid being drawn off. After a tedious operation, owing to the universal adherence of the cyst in the abdomen and pelvis, I succeeded in removing the tumour, the pedicle of which was doubly twisted and adherent to the large intestine. The right ovary was then brought to the surface and carefully examined, and as it appeared to be healthy and was not enlarged it was returned into the abdomen. The peritoneal cavity was then washed out and a drainage-tube inserted and the wound closed with silkworm-gut sutures. The patient made a good recovery, though the pulse was never less than 120 and the temperature kept above 100° till the end of the second week. She left the hospital on June 4th and went to her home, where she remained in good health up to November, 1892, when she became pregnant. Her health was excellent up to July 20th, 1893, at which date she was delivered of a still-born male child which weighed over 11 lb. The presentation was a breech one and the labour very tedious. The child was alive at the commencement of labour; but owing to the unusual size and the marked deficiency of expulsive power, notwithstanding the administration of ergot, it was impossible to save his life. The placenta came away easily and the patient went on well and got up on the eleventh day. It was remarked after delivery that the mother was as slight as ever she had been, and Dr. Seccombe is confident that no swelling other than the contracted uterus could be detected in her abdomen. On the fifteenth day, however, when up and about she had an attack of pain in her right

Hosted by Google

side which compelled her to go back to bed, where she remained a couple of days, when the pain passed off and she thought no more about it. A month after her delivery she noticed that her abdomen was rapidly becoming enlarged, and later she sent for Dr. Seccombe, who examined her and found a large cystic swelling on the right side of her abdomen. He wrote at once to me, and on Sept. 1st I saw the patient with him and confirmed his diagnosis. It was decided that the patient should wait till October, when she could go into the hospital. She was brought to town on Oct. 4th and re-admitted into the Samaritan Free Hospital, where I examined her and found that the tumour had increased so rapidly in the month as to double its size. There was also much free fluid in the peritoneal cavity, and the patient had again become emaciated and was even in a worse condition than when she came up for her first operation. On Oct. 6th she was put under chloroform by Mr. Murray, and assisted by my colleague, Dr. Bantock (Dr. Seccombe and others being present), I opened the abdomen and disclosed a dark-coloured swelling which was adherent to the abdominal parietes and covered by adherent omentum in its upper part. These adhesions were separated and the tumour tapped, thirty pints of dark thick fluid being withdrawn. It was then seen that the tumour had burrowed into the broad ligament and had passed across in front of the uterus between that organ and the bladder, completely stripping off the peritoneum from the anterior surface of the uterus. This portion of the tumour was enucleated and the broad sheet of peritoneum in front of it tied in four pieces, cut across, and dropped back into the peritoneal cavity. The rest of the cyst was then separated from the surrounding adherent intestine and the pedicle transfixed and tied, and the tumour having been cut away the abdominal cavity was thoroughly washed out and drained. The peritoneum was then dissected off for about an inch round the incision and the scar tissue cut away. The wound was then closed with three layers of sutures, a continuous suture of thin catgut for the peritoneum, interrupted sutures of thick catgut for the aponeuroses, and silkworm gut for the skin. The patient made a rapid recovery and went out on Nov. 4th quite convalescent. Curiously enough, after the second operation the pulse and temperature kept above 120 and 100° respectively for the first fortnight, this condition being due to a small abscess in the lower angle of the wound where the tube had rested.

Remarks.—This is the only instance in which I have met with an ovarian tumour burrowing in front of the uterus and displacing the peritoneum between that organ and the bladder—in other words, completely stripping off the peritoneum from the anterior surface of the body of the uterus. Tumours burrowing behind that organ and raising the peritoneum from its posterior surface are not infrequently met with, but the former condition is, I believe, uncommon. It is not often that the growth of an ovarian tumour can be dated with any degree of certainty, but in this case it is certain that, so far as one could judge by sight and touch, the right ovary was healthy on May 4th, 1892. Dr. Seccombe states that after the patient's delivery in July, 1893, no swelling other than the contracted uterus could be felt in her abdomen. A fortnight later the patient had severe pain in the right side, and about a month or six weeks after her confinement her abdomen began to get big, when on examination a cystic tumour was discovered, and this growth increased so rapidly that when seen a month later it was as large again. I presume the disease started during pregnancy, and that after delivery the pressure having been removed the growth rapidly developed, as such tumours usually do under similar circumstances. The first tumour was a large multilocular growth with dermoid material in parts. The second tumour was very similar as regards size, fluid contents, and, so far as one could judge from the history, in the duration and rapidity of growth, but no dermoid material was observed in it. The patient was in excellent health on Feb. 23rd, 1896.

HIS ROYAL HIGHNESS THE DUKE OF YORK has consented to preside at a dinner in aid of the funds of the Association for the Oral Instruction of the Deaf and Dumb, 11, Fitzroy-square, W., on Wednesday, March 17th, 1897, at the Hôtel Métropole. An appeal is made for the £7000 required to free the association from debt and to purchase the freehold of the premises.

THE INSIDIOUS MARROW-INFECTION OF MAMMARY CARCINOMA.

BY HERBERT SNOW, M.D. LOND.,
SURGEON TO THE CANCER HOSPITAL.

Prevalence.—Secondary deposit within the bone-marrow is a pronounced event in 8 out of every 10 cases of carcinoma mammæ passing to a fatal termination. Whether the remaining 2 are completely exempt to the end is at present doubtful. Of 150 seen in the out-patient room at an average duration of from ten to twelve months, 90 showed well-marked symptoms of this peculiar condition at their first visit, 22 showed symptoms in a slighter degree, and 8 developed them subsequently under observation; total 120, or 80 per cent. The physical signs were absent or doubtful in 30, which fall into two classes, those too recent to betray them, and "atrophic" cases. Thus 12 were of from six weeks to six months' duration only and 4 from six to twelve months. Of the remainder, 12 were extremely chronic forms of the disease, which had already existed from two to sixteen years, 5 out of the 12 having grown slowly for more than nine years. It is these "atrophic" cases in women that alone show prolonged exemption from the marrow lesion; the breasts are previously scanty or shrivelled, approaching the male type; life is not terminated for a long term of years, sometimes for more than twenty or thirty, and the exemption aforesaid largely accounts for this peculiar chronicity.

Mechanism of the infection.—Average examples of mammary scirrhus in women infect the lymph glands within the corresponding axilla in from six to twelve weeks from inception. The malignant cells quickly block the lymph sinuses and diversion of the current takes place in abnormal directions. These glands receive lymph from the marrow of the adjoining humerus; when they become cancerous regurgitation ensues, and thus deposit takes place within this bone, ordinarily the first affected. Again, from the inner edge of the mamma a few lymphatics normally pierce the thoracic wall and convey lymph to the mediastinal lymph glands and also to the thymus, a lymphoid organ whose rudiments are never wholly obliterated, but persist through life as a fatty mass immediately behind the sternum at the junction of its upper and middle portions. Thus malignant cells reach the thymus, and, there proliferating, directly invade the sternum. In the third place, and usually after a considerable lapse of time, fragments of cell-protoplasm pass from the marrow into the blood-current and thence invade other bones, the opposite breast, or the viscera. The above is the ordinary route; but as the infection is a mechanical process it is to be noted that interference with the normal lymph-current (as by an operation and its resulting scar in the axilla) may preclude infection of the humerus, the flow then passing wholly to the mediastinum and thymus.

Symptoms.—The physical signs of marrow-infection are rarely evident until the disease has existed eighteen months and may be delayed much longer. They are threefold, and to be classified in relation to (*a*) the humerus, (*b*) the sternum, and (*c*) the quasi-rheumatic pains in the loins and scapulæ. The upper third of the humerus becomes tender on pressure, apparently from irritation of the periosteum; the bone also feels slightly thickened in comparison with that on the opposite side. The sternum displays a very slow and gradual bulging forward at the junction of the upper and middle portions; it is painless and is seldom noticed by the patient until her attention is directed thereto. It proceeds only to the development of a sufficiently conspicuous prominence and then stops, resulting in actual tumour formation only in from 2 to 3 per cent. Lastly, the quasi-rheumatic pains are a late phenomenon and are referred to the lumbar region, scapulæ, and arm of the same side as the lesion. They are deeply-seated, described as "gnawing" or "aching," are, like ordinary rheumatism, worse at night and alleviated by salicylates, but, unlike that, do not affect the articulations. In advanced cases there is extreme physical weakness with emaciation, due seemingly to the cytogenic function of the marrow.

Diagnosis.—The sternal prominence may be simulated by

Hosted by Google

natural conformation of the part. It is only when this occurs in association with the gnawing lumbar and scapular pains, and particularly when its gradual development has taken place under observation, that full reliance can be placed thereon as pathognomonic of the infection.

Morbid anatomy.—Deposit within the medullary canal of a long bone results in "white" marrow. That substance is converted into a relatively firm material as white as note-paper; the existence of this suffices to indicate carcinoma without microscopic examination. With the cancellous tissue of short and flat bones the test does not hold; the marrow is not altered in colour or in consistency, even when full of cancer-parenchyma, and the presence of the latter can only be established by the microscope. Decalcification takes place, however, under all circumstances, when there is cancer deposit in a bone. On exposing the head of a humerus so affected the point of the scalpel can be readily pushed into the greater tuberosity—a rough test I have not yet known to fail. In advanced cases, those, for instance, in which brawny œdema of the arm is present, the bone can be sliced with the knife as readily as the soft parts.

The following are typical cases showing the clinical course and the average chronicity:—

CASE 1.—A woman aged forty years had her left breast with enlarged axillary glands removed in June, 1887, for scirrhus of a year's duration. No marrow symptoms were then present. She was not seen again till December, 1892, when the sternal condition with the quasi-rheumatic pains were present, but there was no other trace of cancer. In December, 1893, two small nodules were found close to the sternum, and shortly afterwards a third, while the patient's health became impaired.

CASE 2.—A woman aged fifty-four years in January, 1881, underwent excision of the left breast and enlarged glands for scirrhus of one and a half years' duration. In March, 1884, the sternal symptom was conspicuous, but there was no other indication of cancer. In February, 1885, the original scar was still perfectly healthy, but there was a mass of enlarged glands in both axillæ. The patient is still strong enough to work as a domestic servant.

CASE 3.—A woman aged sixty-one years had a large carcinoma of about two years' duration excised in July, 1886, the size of a small orange; the axilla was also cleared. There was no re-attendance until June, 1893; then the sternum was so prominent as almost to constitute a tumour; there were a small subcutaneous nodule over the xiphoid cartilage and a cluster of enlarged glands in the opposite axilla, but the scar was healthy. In July, 1893, the patient died from paraplegia through deposit in the vertebræ.

CASE 4.—A woman aged sixty-four years was seen in August, 1888, with a breast scirrhus of eighteen months' duration following on cyst of twenty years' duration. Operation was declined till August, 1892, when there were a large sore and a mass of glands in the axilla, and the sternal prominence was well marked. In June, 1895, a nodule the size of a bean appeared under the scar, there were lumbar pains and sternal prominence, but otherwise the patient was in good health.

CASE 5.—A woman aged sixty years had the left breast excised in October, 1888, for a large acute carcinoma of probably two years' duration. In January, 1889, the sternal symptom had developed, with no other palpable deposit. This was followed in the succeeding July by implication of the opposite breast.

Non-insidious cases.—I have only five or six times seen the sternal protuberance proceed to actual tumour-formation with subsequent ulceration. In a small percentage only of the total cases does the marrow infection betray itself in this way by tumour growth, or, secondly, in a long bone by spontaneous fracture, or, thirdly, in the vertebræ by distortion or paralysis. All the specimens so far preserved in museums belong to this non-insidious category, in which some obvious lesion has induced examination of the particular bone in question. The bones, again, have often been mounted as "dry" specimens of "fragilitas ossium," or absorption of lime salts, the actual presence of cancer-parenchyma not having been recognised. Torok and Sprengel found palpable lesion in 12 out of 467 cases = 2·56 per cent.[1]

Inferences and conclusions.—The most suggestive point about this condition is its peculiar chronicity and latency, with the bearing these have on some other obscure diseases in whose phenomena the bone marrow is probably concerned. We find that even in a malady ordinarily so acutely progressive as carcinoma the deposits here may grow unnoticed for from four to five years or more, and they cause hardly any appreciable impairment of health until finally culminating in general diffusion by the blood. The marrow is practically never examined at necropsies unless some palpable lesion there exists; my investigations invite much closer attention thereto. Many of the cases recorded as mollities ossium and osteitis deformans have been found associated with a malignant growth, usually sarcomatous, somewhere in the osseous system,[2] and it seems likely that all will eventually fall into the same category. In malarious countries the bone-marrow of birds is found pervaded by the hæmatophyllum malariæ when absent from the blood. The filaria sanguinis hominis doubtless retires to the same obscure resting place during the corresponding remission period. As a routine symptom marrow infection is shown only by carcinoma of the female breast—this for mechanical and anatomical reasons. It, however, may ensue upon any other form of malignant growth directly implicating the marrow, as in primary sarcomata of bone or in rectal cylindroma adherent to the sacrum. Under none of these latter conditions, however, is it so far known ever to be "insidious."[3] Volkmann's claim of a cure by operation when there have been three years' apparent exemption is of course negatived, unless marrow-deposits can be confidently pronounced absent.

Gloucester-place, Portman-square.

[1] See paper by Mr. S. Paget in THE LANCET, March 23rd, 1889, showing that marrow-symptoms were not then recognised as due to actual cancer-deposit, or the infection as a routine event.

[2] See list of such in Cancers and the Cancer Process, p. 303.

[3] The above condition was first described in THE LANCET of March 7th and 14th, 1891; subsequently in the *British Medical Journal* of March 12th, 1892, where the detailed cases traced to a necropsy may be referred to.

AMPUTATION STATISTICS AT THE LONDON TEMPERANCE HOSPITAL.

BY W. J. COLLINS, M.S., B.Sc. LOND., F.R.C.S. ENG.,
FELLOW OF LONDON UNIVERSITY; SURGEON TO THE LONDON TEMPERANCE HOSPITAL AND TO THE ROYAL EYE HOSPITAL.

THE following table has been prepared for me by Dr. Leonard Wilde, the registrar to the London Temperance Hospital. It includes all the amputations which I have performed there since my appointment as surgeon to the hospital in succession to Mr. Pearce Gould in 1888.

Table showing Amputation Mortality from July 1st, 1888, to Dec. 31st, 1896.

	For disease.		For accident.	
	Cases.	Deaths.	Cases.	Deaths.
At hip	4	—	—	—
Of thigh	9	1	2	—
Of leg	7	—	5	—
Of foot	6	—	—	—
Of toes	12	—	—	—
Of arm	—	—	2	—
Of forearm	2	—	—	—
Of hand	—	—	1	—
Of fingers	19	—	6	—
Total	59	1	16	—

The grand total is 75 cases with 1 death.

The following are the notes of the one fatal case, in which amputation of the thigh was performed for sarcoma of the ham, and in which the post-mortem examination showed pre-existent secondary growths in the liver and pelvis.

A man aged forty-nine years was admitted on March 27th, 1891, on a medical certificate stating that he was suffering from phlebitis. He had been ill for six weeks with pains behind the left knee and down the leg, with œdema of the

Hosted by Google

foot and lameness. On admission to hospital the left knee was flexed and could not be straightened, and movement of it occasioned some pain. There was a swelling as big as a duck's egg occupying the site of the head of the fibula and extending into the popliteal space. The patient had lost flesh lately, looked more than his age, had had recent trouble (having lost his wife), and wandered a little at night. The case was diagnosed by me as sarcoma of the ham, and amputation at the thigh was recommended should an exploratory incision into the tumour confirm the diagnosis. On April 3rd amputation at a little below the middle of the thigh was performed under chloroform. He bore the operation very well. For a week following the operation the temperature fluctuated between 98° and 103°F. The delirium at night was more marked. On the 11th he had intractable diarrhœa, was delirious, and was losing ground. On the 13th he was passing urine and motions involuntarily. Ether (6 drachms in the twenty-four hours) was ordered. On the 14th the temperature was running higher; there was continuous involuntary diarrhœa unchecked by opium, and he was busily delirious and sleeping badly. The pulse was very rapid—140 and more. Spiritus vini rectificatus was ordered, one drachm to be given every four hours with egg and milk unless he was drowsy. On the 15th he had no sleep; he still took food fairly well. There was no bed-sore. The alcohol was continued every six hours. On the 16th he died.

Post mortem secondary deposits of sarcomatous nature were found in the liver; a large cavity containing new growth occupied the iliac region; there was also an abscess in the *right* inguinal region. There was scarcely any tendency towards repair in the flaps, but there was no osteomyelitis or tracking of pus. The other organs were healthy.

In two of the above cases only was alcohol in any form administered, the case just related being one of the two. The other case was one of amputation of the leg for embolic gangrene in a flabby woman aged forty-nine years with cardiac disease, who recovered. Full details of this and of all other cases in which alcohol is administered are set out in the annual reports of the hospital in accordance with Rule XV. of its constitution, which provides that: "It shall be incumbent on the prescribing medical officer, in any case where alcohol in any form is ordered for a patient, to enter in a book kept for that purpose the full particulars of the prescription, including the time, quantity, and reasons of administration. The effect of the dose also shall subsequently be noted."

Albert-terrace, Regent's-park, N.W.

SCHOOL-MADE INSANITY.

BY LL. HARRIS-LISTON, M.R.C.S. ENG., L.R.C.P. LOND., L.S.A.,

ASSISTANT MEDICAL OFFICER, HOSPITAL FOR MENTAL DISEASES, COTON HILL, STAFFORD.

THE classical statement made by the old-time surgeon, that no injury to the head which produces insensibility is too trivial to be disregarded or too serious to be despaired of, is one the truth of which is frequently in evidence. A case which has recently been under my observation may be quoted as an example, and for other reasons is, I think, worthy of record. It is a case in which a few blows given with the open hand on the side of the head by one boy to another was the exciting cause of attacks of insanity of some years' duration. Although no cause for an attack of insanity is more frequently assigned by parents than a fall or blow on the head during infancy, on investigation some more probable factor is generally to be found. In the report of the Lunacy Commissioners for 1896 3 per cent. only is the proportion of cases in which injury is given as the predisposing or exciting cause in all cases admitted into asylums, hospitals, or licensed houses during the five years 1890–94. In this case the hereditary history is remarkably clear of all nervous diseases, the only instance being an attack of senile dementia in the patient's paternal grandfather at an advanced age.

The first attack began when the patient, then sixteen years of age, was at school, the symptoms being mental depression, sleeplessness, pain in the head, unsociable habits, and loss of nutrition coming on within two months of the injuries. He was taken from school, and after spending a few months at home recovered his natural spirits, became a clerk, and remained well for two years. Then, at eighteen years of age, he had an attack of acute mania, for which he was treated at a lunatic hospital and from which he recovered in eight months and resumed his work as a clerk. For six years he remained well, spending the last year of this period in Canada farming. Then, becoming depressed, fearing that he was about to have another attack, and feeling self-conscious amongst strangers, he lost all interest in his work and, without giving his relatives any warning, suddenly arrived at home. He gradually got worse in mind and body, became despondent, silent, morose, lost all energy, avoided society, refused food, and became emaciated and weak; therefore, he was certified again and admitted, at the age of twenty-five years, to a lunatic hospital, where he became more confused and obstinate and in a few months sank into a state of stupor. After twelve months' residence in this hospital, as he became no better, a change of environment was advised and he was transferred to another asylum, where I first saw him. He was then in a state of melancholic stupor, being resistive and conscious, with a miserable, furtive expression, standing in one place and in the same attitude for hours, with a hand pressed to the head or stomach, taking food unwillingly and sparingly, answering no questions unless repeatedly urged, and then only giving a monosyllabic reply. He was unsettled, restless and sleepless at night, thin, with flabby muscles. The pulse was 64 and weak, the temperature 97° F., the bowels constipated, the extremities cold, and the circulation poor. He remained in this state for two years longer, the state of stupor having lasted altogether for three years, then he gradually began to take some interest in his surroundings and answer simple questions in a whisper. He was then induced to do some outdoor work, and in three months gained flesh and some confidence, but still thinking badly of himself and of his bodily condition. Questioned as to his past state of stupor he said that he remembered everything that had happened around him and that he had often crept away to avoid observation when strangers visited the hospital, that he had feelings altogether different from, and bodily sensations strange to, those he had when in health. In a few months more he still further improved, getting strong in body, slightly hypochondriacal, but having some hope of regaining a position in the outside world. He was discharged as recovered. The treatment of his last attack consisted of giving quinine and strychnine in large doses, malt extract, plenty of food and alcoholic stimulants, warm baths, cold douches, and latterly of manual work out of doors, bicycling, golf, swimming, cricket, &c.

The causation of this case is its interesting feature: blows on the head with the open hand severe enough to cause unconsciousness on at least two occasions, without a lesion of the bone, but producing some molecular disturbance of the brain sufficient to excite insanity. The injury was inflicted as punishment for some minor offences by one of a body of boy prefects, who at the school the patient attended were allowed disciplinary powers, one being to strike a boy on the head, apparently as often and as hard as they deemed advisable; surely a dangerous power to entrust to boys. There are other contributory conditions in the case only prevailing at this period of life, and which exist at many other schools, and which have caused me to call the case "school-made": the age of puberty, one of the periods of life at which nervous diseases are prone to appear; the reprehensible practice of working scholars in the early morning before breakfast and after a long fast; and the emotional influence of constantly recurring religious services carried out in some schools to a ridiculous extent.

Stafford.

THE secretary of the East London Hospital for Children calls attention to the need of funds for current maintenance, and of from £1000 to £1500 to complete the estimated cost of the Convalescent Home which the managers are about to erect at Bognor.

THE total of the subscriptions for the Memorial erected over the grave of the late Mr. Reese of Ystradgynlais, who was killed by lightning on July 21st, 1895, has reached the sum of £102 0*s.* 11*d.*

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF IRIDECTOMY SUCCESSFULLY PERFORMED BY ACCIDENT.

BY HAYDN BROWN, L.R.C.P., L.R.C.S. EDIN., L.F.P.S. GLASG.

A FEW weeks ago two children were playing together near a garden seat. One of them had a pair of scissors in her hand, with the points sticking out, when the other toppled over in some way and brought her left eye in contact with a point of the scissors, which were held firmly in the hand as it chanced to lean on the seat. The result was that the eye was pierced at the corneo-sclerotic junction, or perhaps a line above it. A cut was made one-third of an inch long and slightly curved. The point of the scissors entering the anterior chamber went so far as to hook down the iris into the opening, and on withdrawal left it there. I saw the child about an hour after the accident, and having put in an atropine lamella ordered boracic lotion to be used three times a day, ice pretty frequently, and the eye to be kept closed by a bandage. The inflammation of the conjunctiva and iris was rather severe for a few days. The chances of the fluid coming out of the eye had already been so great—and there probably had been some escape, but I did not see it—and the appearance of the cut was such, that I decided at the outset not to attempt to put back the hooked-down iris, which seemed to be cut a little also. This portion, trapped as it was in the wound of the cornea, eventually became absorbed in the cicatrix. There has been complete union for four weeks and entire absence of inflammation, whether of conjunctiva, cornea, or iris. The present condition of the eye is quite indistinguishable from one on which an iridectomy has been most skilfully performed; indeed, it would be difficult to find a case more neatly and perfectly done, and the sight is correspondingly excellent.

Buckhurst Hill.

A CASE OF MERCURIAL POISONING.

BY T. GREENWOOD HALL, M.B., B.S. DURH.

ON Nov. 27th, 1896, I was summoned to a female patient whom I had a week previously attended for a miscarriage. I had ordered injections of perchloride of mercury (one soloid in 40 oz. of water = 1:2000) on Nov. 20th night and morning and again on the 26th. I found her on the 27th collapsed and pale, with the pulse rapid, intermittent, and weak, the jaws tightly clenched, and the eyes dull and anxious. She was unable to speak and I could obtain no history of the seizure. There were twitchings of the fingers and facial muscles and she frequently fainted. During the day acute diarrhœa set in, the motions being stringy and containing blood. I discovered that, not having had a motion for two days, she had on the morning of the 27th injected half of the perchloride solution per rectum and half an hour afterwards was seized with cramping abdominal pains, causing the collapse in which I first saw her. She recovered within a week, though complaining of her teeth and gums. Salivation never occurred. The interesting points are the rapidity of action (less than one hour), the smallness of the dose (not more than 5 gr. per rectum), and the fact that the previous injections per vaginam had no deleterious effects.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

SURBITON COTTAGE HOSPITAL.

A CASE OF ACUTE PANCREATITIS; NECROPSY.

(Under the care of Mr. ARTHUR C. HOVENDEN.)

IN THE LANCET of Jan. 2nd we published the account of a case of acute hæmorrhagic pancreatitis in which abdominal section was performed, but without relief. Dr. Newton Pitt in his remarks on the case gave a very useful summary of the present-day knowledge on this subject. The symptoms which are considered by Dr. Fitz to be characteristic of the disease are sudden and severe epigastric pain without obvious cause, followed by tenderness, vomiting, slight rise of temperature, flatulent distension of the abdomen, and complete constipation. To these he added collapse, prostration, feeble pulse, and the presence of a resonant area with deep-seated resistance lying between the umbilicus and epigastrium, and evidences of deep-seated peritonitis. Relief has been afforded by operation in a limited number of cases—in one a tympanitic abscess was opened and drained and the patient recovered; in two others in which collections of pus in the pancreas were similarly treated the patients were only relieved for a time. The close resemblance which is presented to cases of intestinal obstruction by acute pancreatitis makes a correct diagnosis almost impossible, but the condition has been diagnosed correctly during life and the possibility of its presence must be considered when symptoms similar to those mentioned are met with.

A man aged thirty-five years was admitted to the Surbiton Cottage Hospital on Aug. 7th, 1896. His family history was unimportant. He had enjoyed good health, but was somewhat given to alcohol. On Aug. 2nd and 3rd he was quite well, and on the latter day he went to a theatre in town. On the 4th he felt a little out of sorts and took "six" liver pills, but they did not act. On the morning of the 5th he sent for a black draught, which was vomited, and during the morning he was in such pain that a medical man was sent for. When seen by Mr. Bowring the patient was in great pain, which was referred almost entirely to the umbilical region. There was no tenderness or rigidity of the abdominal walls and no tumour or dulness could be made out. Attempts were made to cause an action of the bowel by enemata, but without success. During the whole of this day (the 5th) everything given by the mouth had been rejected. On the 6th he was seen again by Mr. Bowring in conjunction with Dr. Taylor. There was still no rigidity and there had been no movement of the bowels. Dr. Taylor thought there were increased resistance and loss of note in the left hypochondriac region and suggested a dose of calomel in the hope that it might be a case of impacted fæces. This was retained, but although several enemata were administered nothing except flatus was passed. In the evening, however, the patient felt better and several times got out of bed to go to the closet, but passed nothing. On the 7th the patient was evidently worse and was sent to the Surbiton Cottage Hospital. On admission the patient lay on his back in considerable pain; the abdomen was rigid and distended; there was no tumour or dulness to be made out; and a few hours after admission he vomited some dark-brown stercoraceous matter. When on the table for operation he again vomited and stopped breathing during the administration of ether, dying before the operation was commenced. The patient had lived only three days from the time he felt unwell; his temperature was normal throughout.

Necropsy.—On post-mortem examination some early peritonitis was found on the anterior portion of the abdominal wall, the small intestine was a little distended, and the descending colon was flaccid but contained grey-coloured

Hosted by Google

fæces. The pancreas was very much enlarged and of a uniform deep-red colour; the tail of the organ was the size of the closed fist. The liver was large and rather fatty. The kidneys showed a little interstitial change and a couple of cysts. The spleen was healthy.

PRESIDENCY GENERAL HOSPITAL, CALCUTTA.

A CASE OF LOBAR PNEUMONIA FOLLOWED BY GANGRENE OF THE LUNG, AND ONE OF LIVER AND LUNG ABSCESS, IN BOTH OF WHICH OPERATION WAS SUCCESSFULLY PERFORMED.

(Under the care of Surgeon-Captain D. M. MOIR, I.M.S.)

THESE cases further confirm our recent statement of the successful practice of surgery in our colonies, of which we published instances during the past year. They belong to a branch of surgery which has made considerable advance of late, and show what can be done for patients whose condition would have been hopeless only a short time ago. They confirm the conclusions arrived at by Mr. Godlee as to the line of treatment which should be followed. 1. Gangrenous cavities in the lungs should always be sought and if possible opened, and the prognosis, if the operation be successful, is not bad. 2. The same may be said in regard to abscess caused by rupture of purulent collections from other parts into the lungs—at least, as regards the pulmonary complication. The results of treatment in cases of pulmonary abscess in Hofmokl's clinics referred to in the remarks appended to the cases are as follows:—42 cases, 14 cures, 3 had a fistula remaining, 24 died, and in 1 the result was unknown. Five cures resulted after treatment of tuberculous cavities by operation.

CASE 1. *Lobar pneumonia; gangrene of the lung; operation; recovery.*—A man aged twenty-three years had an attack of acute pneumonia of the left lung at Jamalpur on Feb. 13th, 1896. As he did not improve he was taken to Calcutta, a distance of 300 miles, and was admitted into the European General Hospital on March 8th, the twenty-fourth day of his illness. From the symptoms on admission the case appeared to be one of lobar pneumonia, in the stage of resolution, accompanied by slight pleural effusion. He looked and felt very ill and prostrate, and the clearing up of the pneumonic consolidation seemed to be unnaturally delayed. In the course of the first week in hospital his sputa became intensely fœtid, greenish-grey in colour, purulent and nummular. He passed restless nights owing to frequent distressing paroxysmal cough. In the second week he suffered a good deal from diarrhœa and profuse perspiration. It was evident that septic absorption was going on and the physical signs pointed to gangrene of the lung. The temperature was irregular, rising from normal to 103° F. In the third week attacks of hæmoptysis supervened. The cough was very troublesome; the sputum was very offensive, copious, and coffee-coloured, with exhausting sweats and intense prostration; and the diarrhœa recurred. However, the patient's dread of chloroform and of the knife was so great that he did not consent to undergo an operation until his condition had become almost hopeless. The operation was performed at noon on March 28th—i.e., the twenty-first day in hospital and forty-fifth day of his illness. From the physical signs, which were best marked in the axillary and infra-spinous part of the scapular region, it was evident that the gangrenous portion of lung was on a level with the mammary region (from the third to the sixth ribs), and that the most suitable place for incision and drainage would be between the fifth and sixth ribs in the axillary area. Accordingly, a horizontal incision two inches long was made in the fifth intercostal space of the left side, which was followed by the escape of a small quantity of fœtid purulent fluid and débris. By the finger it was ascertained that the axillary part of the pleural cavity corresponding to the area of gangrenous lung had been shut off by adhesions from the rest of the pleural sac. On exploring with a Wheelhouse's straight-grooved urethrotomy staff the instrument was found to pass far into the lung so as almost to touch the pericardium; in fact, the impulse of the cardiac systole was transmitted to the staff with startling force and distinctness. Portions of gangrenous lung and pleura-débris and blood-clot were removed with the aid of the fingers, dressing forceps, and a long Volkmann's spoon. A drainage-tube four inches long and three-quarters of an inch in diameter was introduced and an absorbent antiseptic dressing was applied. As so frequently happens in India after an operation the temperature rapidly rose. It had been 97·2° (taken in the mouth) at 9 A.M., 98·2° at 1.30 P.M. after the operation, and by 5.30 P.M. it rose to 103·4°, the highest temperature recorded throughout his stay in hospital. After the first day his temperature caused little or no anxiety, rarely rising to 101°, more usually fluctuating between 98° and 100° during the first fortnight, subsequently to which it gradually returned to the normal. At first the dressings were changed twice daily owing to the profuse discharge, and frequently pieces of slough were removed. The drainage-tubes were gradually shortened and replaced by tubes of smaller calibre, the last of which was finally removed on April 21st, and the wound was quite healed on the 30th. The patient's health rapidly improved and he gained ten and a half pounds in weight between April 21st and May 8th. When he was discharged from hospital on the latter date the following note was recorded: "The percussion note is clear and slightly hyper-resonant in the left axillary region. The breathing is harsh and an occasional moist sound is audible near the incision scar in the fifth space. The lung is soundly healed and he may leave hospital." The patient's mother, who had recently been operated on by Surgeon-Captain Moir, on Sept. 3rd told him that her son resumed work exactly a month after leaving hospital, and that he was then away on a shooting expedition.

CASE 2. *Liver and lung abscess; operations; recovery.*—A man aged thirty-four years, a slim Eurasian of poor physique, was admitted to hospital on Jan. 27th, 1896, complaining of fever, cough, pain in the liver, and enlargement of the spleen. Some years ago while in the Punjab he used to suffer much from malarial fever. In 1888 he had gonorrhœa and a perineal abscess. In 1892 he was treated for abscess and fistula in the perineum. On July 19th, 1895, he was in this hospital for balanitis and diarrhœa. The latter was rather obstinate and continued till the end of the month. On Aug. 1st acute dysentery suddenly supervened lasting for three days, during which time he passed mucus, blood, and a few small sloughs. He left the hospital on Aug. 8th before he had thoroughly recovered. During October and November he was in the Medical College Hospital, Calcutta, suffering from fever and pain in the region of the liver. From Jan. 3rd to 13th, 1896, he was treated in the General Hospital, Calcutta, for hepatitis and was discharged apparently cured, but he returned on Jan. 27th with the symptoms detailed above. The case proved most puzzling. During the first week he appeared to be suffering from ague, with congestion of the liver and spleen—common accompaniments in malarial subjects. From the 27th to the 31st the temperature was intermittent, but it seldom rose above 100° F. In the beginning of February the hepatic pain disappeared, and the temperature remained normal until the 4th, when it rose to 101°. From the 5th to the 20th there was no fever. Notwithstanding this it was quite evident that the man was seriously ill, because he continued to lose flesh and strength. The frequent short dry cough led to numerous examinations of the lungs, but nothing definite was found. The antecedent dysentery and hepatitis early caused a suspicion of liver abscess and the liver was examined nearly every day, but with a negative result. During the first three weeks of February the hepatic pain came and went capriciously. Even the site of the pain varied in an extraordinary way; at one time it was in the right lobe, high up or low down, deep-seated or superficial, whilst at another time it was in the left lobe. Since there was no fever and the symptoms were so obscure it was not considered expedient to make any exploratory punctures in the liver. However, Nature settled matters in her own way. On the 21st he began to cough up pus owing to a liver abscess having burst into the right lung. On the 20th his highest temperature was 99°, and on the 21st 99·4°, after which it remained normal until the 26th, when it rose to 101·4°. There were also slight rises on the 27th and the 28th. As many cases have been recorded in which recovery has followed the discharge of a liver abscess into either the lung or the bowel, and as there were no unfavourable symptoms, it was decided that no operation was necessary. In March, however, his symptoms became unfavourable and gave cause

Hosted by Google

for anxiety. Between the 1st and the 13th the temperature remained normal most of the day, but usually there was an evening rise between 5 and 9 P.M. to 99° or 99·6°. In fact he was suffering from hectic fever. The cough became very troublesome and the expectoration copious and he had profuse perspirations with restless nights, consequently it seemed advisable to try to drain the liver abscess. On March 13th after using the exploring needle, a horizontal incision two and a half inches long was made in the sixth intercostal space two and a half inches below the right nipple. On pushing the finger through a thickish layer of liver substance the abscess cavity was reached. Ten ounces of pus were evacuated and a large-sized drainage-tube was inserted. It was not possible to palpate the aperture of communication through the diaphragm into the lung. On the next day his temperature was normal and he had neither cough nor expectoration. The drainage-tube was gradually shortened and changed and was finally removed on the 24th, at which time the track was scarcely more than an inch long. On the 30th he weighed 105 lb.—a gain of 2 lb. since the last weighing. four days prior to the operation. During the first week of April the cough again became troublesome and the sputa were viscid, greenish, and nummular. At this time the percussion dulness began one and a half inches above the right nipple and merged into the liver dulness. By the 9th the wound was completely healed. The temperature remained normal and he gained steadily in weight. On the 21st he weighed 114 lb.—a gain of 11 lb. since the weighing previously to the operation. After this date, however, there was a relapse. The fever returned and the temperature varied from normal to 102°. The cough became most distressing and the expectoration very copious and purulent, and there were occasional attacks of hæmoptysis. His feet became œdematous, he suffered from exhausting sweats and restless nights, and his appetite failed. The physical signs indicated excavation of the right lung in the axilla and about the mammilla. Accordingly on May 5th an incision was made far back in the right axilla over the fifth rib, one inch of which was resected. After puncturing the lung and dilating the passage a small cavity was found which extended upwards and inwards above the level of the nipple. This communicated with another cavity, below the nipple, which led down to the diaphragm. By introducing a metal bougie, the curve of which was convenient, a counter opening was made in front in the fourth space below the nipple and above the scar of the incision into the liver abscess. Some lung débris, pus and blood were evacuated from the lower cavity in the lung. Through the axillary incision a drainage-tube over three inches long and half an inch in diameter was introduced into the upper cavity. A drainage tube nearly five inches long and three-fourths of an inch in diameter was passed in from the anterior incision, through the lower cavity and towards the lateral incision. He passed a restless night and complained of great pain in the epigastrium. On the next day (the 6th) the dressings were soaked with copious discharge, and the expectoration contained blood and pus. The highest temperature was 100°. After another restless night his temperature was normal (on the 7th) and the discharge and expectoration were much diminished. He began to improve, but the drainage-tubes were a constant source of trouble from the difficulty of retaining them *in situ*. They were gradually shortened and changed for smaller ones and were finally removed on the 23rd. The wounds closed rapidly. On the 29th he was carried downstairs and weighed for the first time since April 21st. It was found that he had lost 20 lb. 8 oz., his weight having fallen from 114 lb. to 93 lb. 8 z. During June he steadily gained weight and on the 26th he weighed 108 lb. 8 oz. His fingers and toes became markedly bulbous or clubbed. There were various ups and downs in the progress of his convalescence, which was very gradual and tedious. In the second week of July he was able to be out of bed and it was noticed that he tended to lean over on the right or affected side in walking. The expansion of the right side of the chest was defective. On July 24th his weight was 113 lb. 11 oz., which was nearly as much as it had ever been while he was under observation. During the latter half of July he improved rapidly in every way, so much so that he was fit to be discharged from hospital and to be sent to the Eden Sanatorium at Darjeeling on the 29th. At this time there was comparative dulness over most of the right side of the chest in front, and the pectoral muscles on this side were atrophied. The expiration was prolonged and the breathing slightly harsh, but there were scarcely any accompaniments, except some medium râles at the anterior border of the axilla on a level with the nipple, and also posteriorly about the same level. The expectoration was very scanty, greenish, and muco-purulent. The ungual phalanges of the fingers and toes were distinctly clubbed. Since the patient left the hospital Surgeon-Captain Moir has had good accounts of him from time to time. The last report, dated Sept. 9th, was from the assistant surgeon in charge of the Eden Sanatorium, who stated that "he is doing very well, has no bad symptom of any kind at present, and weighs 127 lb."

Remarks by Surgeon-Captain MOIR.—As regards Case 1, gangrene is not a common sequel to acute pneumonia, and when it does happen it is usually in the case of an alcoholic or aged person or when pneumonia is an intercurrent complication of some other exhausting disease. But pneumonic gangrene in a previously healthy young adult must be of rare occurrence. This patient was a strong young man leading a healthy life as a fitter in the railway workshops, who devoted most of his spare time to out-door sports. In his case the excision of a portion of a rib was distinctly contra-indicated, nor did it seem advisable to syringe out the cavity, although this procedure is advocated on good authority. One practical difficulty in the treatment of such a case is the great tendency there is for the drainage-tube either to slip out or be extruded, and also the rapidity with which the track of the tube contracts once the latter is expelled. Nevertheless, it is essential to maintain effective drainage until both expectoration and discharge have ceased. Regarding the statistics of operation for gangrene of the lung Dr. Pendleton Dandridge[1] makes the following statement: "Of the result in gangrenous cases Lopez reports seventeen cases of gangrene treated by opening the cavity, followed by ten cures, six deaths, and one 'unknown'; Hofmokl, twenty-four cases, with seven cures, one unimproved, thirteen deaths, and two unknown, whilst in one a fistula remained."

PATHOLOGICAL SOCIETY OF LONDON.

The Biology and Morphology of the Tetanus Bacillus.—Exhibition of Specimens.

A MEETING of this Society was held on Jan. 5th, the President, Mr. H. T. BUTLIN, being in the chair.

Dr. A. A. KANTHACK and Mr. W. T. CONNELL read a paper (with lantern demonstration) on the Biology and Morphology of the Tetanus Bacillus. On gelatin the colonies are numerous but very minute and give rise to liquefaction in seven to eight days. On agar-agar there are also numerous and minute discrete colonies which do not coalesce, the surface ultimately having a beautifully crystalline appearance. Impression specimens show that the colonies consist of a close network of filaments sending out branches in different directions. Some of the bacilli are clubbed. The clubbing and the filamentous arrangement point to a mycelial ancestry of the tetanus bacillus. In old broth cultures spore-bearing bacilli are common, the bacillus having a drumstick shape, the terminal knob of the drumstick staining faintly or having a deeply stained central dot. True mycelial forms are common in young cultures, resembling those of the bacilli of tuberculosis and typhoid fever described by Klein. The tetanus bacillus has not one terminal flagellum as usually described, but from twenty to thirty situated all over the bacillus are seen in young cultures; they are long and tortuous, two or three being much coarser than the rest. The flagella gradually disappear when the spore is formed. The drumstick often shows a sheath perforated by numerous channels through which the flagella had passed.—Professor CROOKSHANK had for years observed many of the appearances described and had figured the filamentous forms. After staining by the Ziehl-Neelsen method he had seen the variations in the position and size of the spores. The flagellation of the spores had been very beautifully demonstrated by Dr. Kanthack and Mr. Connell and was a new

[1] Annals of Surgery, xix., No. 2, February, 1894.

Hosted by Google

observation. He thought that the branching forms indicated a tendency for lower organisms to develop into the higher streptothrix group rather than that the organisms were degraded from a mycelial ancestor.—The PRESIDENT asked what was the cause of death of the animals into whose peritoneum the cultures were inoculated.—Dr. KANTHACK, in reply, said that he thought the bacilli directly caused death, but without characteristic symptoms, because care was taken that no toxins were injected at the same time. He did not claim any priority for his observations on the filamentous forms, but was not aware that mycelial forms had been described before.

Dr. DREW showed a specimen of Villous Papilloma becoming Malignant, situated in the Pelvis of the Kidney. It occurred in a man aged fifty-six, who had pain and hæmaturia, suggesting renal calculus, and nephrotomy was performed. At the necropsy a few months later there was great enlargement of the left kidney by an internal growth which infiltrated the cortex, with enlargement of aortic and lumbar lymphatic glands. There was also growth extending into the ureter and another papillomatous growth in the bladder. The growth in the kidney was formed of a fibrous stroma enclosing spaces containing spheroidal cells and often papillomatous projections. A similar condition was found in the lymphatic glands, but the growth there was more definitely carcinomatous. He referred to eight other recorded cases of papillomatous tumours in the pelvis of the kidney. In several of these a calculus was also present.—On the suggestion of Mr. CLEMENT LUCAS the specimen was referred to the Morbid Growth Committee.

Mr. J. R. LUNN showed: (1) a specimen showing Excision of the Knee removed three years after operation; (2) Femur of a woman aged seventy-two years, whose external condyle had been trephined and the button of bone replaced thirty days before death; (3) Breast of a man aged ninety-one years removed for a fungating growth. Sections showed it to be one of duct carcinoma.—The PRESIDENT said that in a case of his own referred to recurrence occurred three years later. As a rule, recurrence was less rapid in duct carcinoma than in other forms of mammary cancer.—Mr. RAYMOND JOHNSON gave reasons for regarding the tumour as a duct cancer. Villous cancer was a term that led to confusion. He thought that duct cancer was more malignant than was generally taught. — Mr. SHEILD was inclined, after careful examination, to regard the specimen as a scirrhous cancer. He thought that the absence of cysts was against the diagnosis of duct cancer.—Dr. KANTHACK agreed with Dr. Johnson that the hardness of the tumour did not exclude columnar-celled cancer. He also had often noticed that in rapid growths, and in secondary growths the columnar character of the cells was often lost. He thought the sections were those of columnar-celled carcinoma —Dr. ROLLESTON thought the specimen was a columnar-celled carcinoma of an aberrant type —Mr. SHATTOCK took the same view.—The PRESIDENT referred to the transition of type of cells seen in Paget's disease of the nipple. He thought the case was clearly one of columnar-celled carcinoma..

Dr. CALVERT showed a Tooth-plate which had been impacted in the œsophagus of a young woman for eight months with scarcely any symptoms. She suddenly vomited some blood and died a few hours later. It was found that one flange of the plate had ulcerated into the thoracic aorta.

The following card specimens were exhibited:—

Dr. PARKES WEBER: Cardiac Thrombosis without Valvular Disease.

Dr. TH. FISHER: Broncho-pneumonia with Dilatation of Bronchus.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Some Points in Abdominal Surgery.—Exhibition of Specimens.

A MEETING of this society was held on Dec. 16th, 1896, Dr. W. B. RANSOM, President, being in the chair.

Dr. TRESIDDER read a paper on Some Points in Abdominal Surgery. Referring to shock in operations on the peritoneum he first drew attention to the peculiarities of the peritoneum —viz., its considerable surface, its great sensibility, its remarkable powers of absorption, and its wonderful powers of healing. The amount of shock in operations on the peritoneum, among other things, would depend on (1) whether it had been previously operated on; (2) the region of the operation; and (3) whether the membrane was inflamed. With reference to abdominal cysts he thought that it was important clinically to ascertain (1) whether they were unilocular or multilocular; (2) whether they were pedunculated or sessile; and (3) whether adhesions existed. In the treatment of cysts deep in the pelvis he had found Trendelenburg's position very valuable. Lastly, with reference to uterine cancer. He had recently performed four operations of vaginal hysterectomy for cancer; in two of these mental complications had occurred, one patient dying from melancholia and the other with recurrence with marked mental depression; the remaining two patients were alive, but one now had recurrence, five months after the operation, and the other was well still, eleven months after. He considered that the limits of complete vaginal hysterectomy were very narrow, and he now preferred supra-vaginal amputation of the cervix, as mental complications were much less likely to follow this operation and, moreover, anatomically the disease tended to spread not upwards to the body of the uterus but in the line of the lymphatics outwards into the broad ligaments. He illustrated points in his paper by a table of seventeen cases of various abdominal diseases that he had recently treated by operation.—The PRESIDENT and Mr. A. R. ANDERSON made remarks on the paper, and Dr. TRESIDDER replied.

Dr. TRESIDDER also showed the following pathological specimens—(1) Stomach showing Healed Gastric Ulcer after Operation; (2) Double Uterus with Pyosalpinx; (3) Five Ovarian Cysts; (4) two specimens of Double Pyosalpinx; (5) Carcinoma Cervicis Uteri; (6) Carcinoma Corporis Uteri, and (7) Microscopic Specimen showing Alveolar Carcinoma of the Body of the Uterus.

The PRESIDENT showed a microscopic specimen of an Alveolar Sarcoma of the Skin.

Mr. ANDERSON showed (1) a specimen of Double Pyosalpinx; and (2) Primary Lympho-sarcoma of the Inguinal Glands with microscopic specimen. He gave also a short clinical history of this latter case, which ran a rapid course, destroying life in two months.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Specimens.

A MEETING of this society was held on Dec. 17th, 1896, Dr. PORTER being in the chair.

Mr. PYE-SMITH showed a woman, aged fifty-eight years, with a large Cystic Tumour of the Neck probably congenital. The tumour was first noticed when the patient was seventeen years of age. It grew to the size of a child's head, and burst when she was forty-nine years of age, discharging fluid blood and continuing to bleed for three days, greatly reducing her strength. It healed and burst again when she was fifty-six years of age and again (twice) a year later. Since then it has never quite healed and now fresh openings are appearing. It always became inflamed before bursting and at present it is somewhat inflamed.

Mr. PYE-SMITH also showed a case of Staphylorrhaphy in which he had used a continuous instead of an interrupted suture.

Dr. ARTHUR HALL showed the following cases: (1) Pityriasis Rosea in a man aged twenty-eight years—the duration of the disease was three weeks; (2) Circinate Papulo-squamous Syphilide of the Chin and Cheeks; and (3) Aortic Stenosis in a young woman with an extremely loud rough systolic murmur, the secondary effects and symptoms being practically nil.

Dr. CUFF showed a case of Tuberculous Lymphadenitis. The glands on the opposite side of the neck were also involved.

Dr. ALFRED ROBINSON (Rotherham) showed a Tongue which had been removed from a two-year-old bullock suffering from Actinomycosis. The case occurred in the winter months, and several other cattle from the same farm had been suffering from a similar complaint. The diagnosis was verified by microscopical examination.

Mr. CYRIL FLORY showed a case of Left Pneumothorax in a man aged fifty years, a silver turner by occupation. The patient's account was that whilst at work on Nov. 1st he felt as if something had given way. He became suddenly very short of breath and broke out into a sweat. There was a history of winter cough for several years, but no injury or any evidence of tuberculosis. The heart was much displaced,

Hosted by Google

the apex being on the right nipple line. Though the condition had existed for over six weeks there was no fluid in the chest.

Mr. CONNELL gave particulars of a case of Primary Ventricular Cerebral Hæmorrhage and showed the specimen. The subject, a man forty-six years of age, was found in a fit about half an hour before he came under Mr. Connell's observation in the Casualty Room of the General Infirmary. His face was cyanosed, the breathing stertorous and purely diaphragmatic, and the pulse 66, full and bounding. The pupils were dilated and did not react to light, and the limbs were markedly flaccid. The specific gravity of the urine was 1010 and it contained a large quantity of albumin. Uræmia, hæmorrhage into the pons, alcoholic intoxication, opium poisoning, and injury to the spine were thought of, and the diagnosis of hæmorrhage into the lateral ventricles was made during life. This was confirmed by the necropsy. The kidneys were slightly granular and the cortex thinned. The left ventricle was hypertrophied.

Dr. BURGESS showed a girl aged six years with Pulmonary Regurgitation from Congenital Heart Disease. There was a diastolic thrill and murmur in the pulmonary area. The murmur was conducted to the left and heard down the left side of the sternum. Over the aortic area and along the vessels the click of the valves could be made out. The apex was displaced outwards and there was epigastric pulsation. The heart affection was first noticed when the child was about a year old. There was no family history of rheumatic fever.

Dr. PORTER, Dr. HALL, Dr. WHITE, Dr. CUFF, Mr. MAKEIG JONES, Mr. PYE-SMITH, and Dr. BURGESS made remarks.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Acute Intestinal Obstruction

A MEETING of this section was held on Dec. 11th, 1896, Mr. WILLIAM THOMSON, President, being in the chair.

Mr. M'ARDLE read a paper on the Operative Treatment of Acute Intestinal Obstruction. The cases quoted were forty-one in number, of which seven were fatal, and included instances of obstruction by bands, intussusception, volvulus, acute enteritis, perforative peritonitis, and appendicular disease. Mr. M'Ardle pointed out that the delay occasioned by trying medicine and enemata often placed the patient beyond the reach of surgery. Prolonged medical treatment was not justifiable, because, as noted by Treves, of 1000 deaths from intestinal obstruction only sixty were from causes removeable by medical means. The chances are all in favour of the obstruction being of such a nature that surgical interference can alone avail. It is therefore to be regretted that some modern writers advocated persistent efforts with enemata, even after dangerous symptoms had shown themselves. Mr. M'Ardle did not advocate indiscriminate laparotomy, but after calling attention to many cases of acute intestinal obstruction in his hospital and private practice in which death occurred before he had an opportunity of operating on the cases he held that with the present safe methods of dealing with abdominal wounds and the rapidity with which Paul's tube, Murphy's button, and such appliances enable us to deal with lesions of the bowel, the intestines should be exposed much earlier and with greater frequency. The points on which greatest stress was laid were—(1) that all fluids should be removed from the pelvis and loins by irrigation with sterile water; (2) that the circulation in the intestines should be restored and peristalsis established by irrigating with boiled saline solution before returning them to the abdomen; and (3) that a tube passed through the rectum should be guided by the hand within the abdomen until flushing of the colon could be thoroughly carried out, so as to reduce the intra-abdominal tension and assist the return of the protruded bowel. When a surgeon is called to a case of complete obstruction of the bowel which has resisted judicious medical treatment and in which evidence of peritoneal effusion exists it is his duty to operate at once.

The PRESIDENT said he was sorry that Mr. M'Ardle had not described the symptoms or methods by which he arrived at the conclusion that those particular cases were cases for operation and not suitable for treatment by ordinary methods.

Mr. TOBIN said that if they applied to all cases of obstruction the rule that they applied in strangulated hernia, they would do well. Who now hesitated to do taxis for the cure of strangulated hernia before any serious disturbance had taken place? An early operation in a great many cases of intestinal obstruction would effect a radical cure. The persons who were most afraid of laparotomy were those who began it too late.

Mr. CROLY was entirely an advocate for early laparotomy in cases of acute intestinal obstruction.

Dr. ALFRED SMITH said that he assisted Mr. M'Ardle in operating on a case in which the patient was so bad that it was not necessary to administer ether before the operation; and he was greatly impressed by the remarkable change that was produced in the intestines by the use of the hot saline solution. It was exactly like the recovery from a cyanosed condition of a patient who had been given too much ether, after the ether bag had been withdrawn from his face. Mr. M'Ardle's experience as to the great advantage of saline solutions bore out that of everyone who had anything to do with abdominal surgery.

Reviews and Notices of Books.

Traité d'Electrothérapie Oculaire. Par le Dr. P. PANSIER (d'Avignon), avec une Préface de M. le Dr. VALUDE. (*Treatise on Ophthalmic Electro-therapy.* By Dr. P. PANSIER (of Avignon), with a Preface by Dr. VALUDE.) Paris: A. Maloine. 1896. Pp. 479. Price 6 francs.

THE employment of magnetism and of electricity in the diseases of the eye is not a new thing; indeed, the application of electricity is briefly mentioned in most of the larger treatises on ophthalmic medicine and surgery, but such notices altogether fail in stating the kind of current that should be employed, whether continuous or interrupted, the strength suitable for the purpose, the position of the poles, and many other details, leading to the suspicion that those who recommend it have seldom or never attempted to use it. Dr. Pansier tells us in the introductory chapter that the magnet has played an important part in the history of superstition. It was held to excite affection, to calm jealousy, to discover adultery, and to re-unite those who have ceased to love. According to Anselm de Boodt, the ingestion of six grains of a magnet so deranges the economy of those who have had the misfortune to swallow them that they are impelled to leave their homes and even to abandon their country. In surgery we learn from Pliny that a powdered magnet was beneficial in diseases of the eye; others tell us that it was used in cases of epiphora. Mylius declares that a magnetic plaster is capable of extracting every kind of venom from wounds. Held in the hands it was believed to facilitate delivery. It was employed in epilepsy and in many other affections, sometimes apparently with success. A second chapter deals with the history of electricity, and the various forms of machines that have been devised for the production of statical and current electricity are described. An account of the electric phosphene is then given—that is, of the luminous sensation that is felt in the eye on opening and closing the constant current; and it is noted that Darier found it serviceable as a means of diagnosis, since in the normal state and in cases of amblyopia without lesion a luminous impression is produced by a current having an intensity of less than a tenth of a milliampère, whilst when the optic nerve is atrophied no phosphene is perceived till the intensity is greater than three-tenths of a milliampère. Dr. Pansier proceeds to consider the effects of electrical currents in numerous diseases of the eye, as in the various kinds of amblyopia, including those of traumatic, hysterical, nicotinic, alcoholic, and strabismic origin; in hemeralopia, in atrophy of the optic nerve, in diseases of the iris, choroid,

Hosted by Google

and retina, in glaucoma, in keratitis and its sequelæ, in paralysis of the ocular muscles, in exophthalmic goitre, and in various affections of the lids, as trachoma, ciliary blepharitis, chalazion, and distichiasis; and there is a section devoted to the use of the magnet. In nearly all these affections references are given to the operator who has employed the remedy, and in many instances a short history of the case is given, with details of the strength and kind and direction of the current employed. In some affections where electricity is rarely employed in this country excellent results have been obtained elsewhere. Thus Driver, Seeger, Meyer, and Adler, as well as the author, have effected the removal of leucomata. On the other hand, great caution is required in accepting the tsatements of enthusiasts. Cataracts, for example, seem to have been occasionally dissipated by electricity. The author cites the case of a woman aged sixty-nine years in whom a cataract in each eye was diagnosed by Professor Agnew. Constant currents were applied by Neftel, the anode being placed on the neck and the cathode on the eye for a period of ten or fifteen minutes. After twenty-five sittings the cataract disappeared and the patient recovered his vision, wearing his former glasses. Unfortunately for this remarkable story, Professor Agnew himself followed up the case and found the cataract *in statu quo*. No change had occurred. It was only an ordinary case of slowly developing cataract. Better results have no doubt been obtained in cases of ocular paralysis and especially in those of exophthalmic goitre, several examples being on record of great amelioration being effected by galvanisation of the sympathetic. The want of a soberly written and critical treatise on the place of electricity in ocular therapeutics has long been felt, and we venture to recommend Dr. Pansier's book as a trustworthy exposition of the present state of our knowledge on the subject.

Life in West London: A Study and a Contrast. By ARTHUR SHERWELL. London: Methuen and Co. 1897. Price 2*s.* 6*d.*

"SUNT lacrymæ rerum, et mentem mortalia tangunt." Mr. Sherwell's book involuntarily reminds us of the above untranslatable line. Here are to be found depths of misery and wretchedness which most of us probably had never dreamed of. Mr. Sherwell mentions in his introduction that Soho, the quarter with which his book chiefly deals, possesses the pathetic interest that always belongs to a neighbourhood that "has seen better days" and incidentally he forecasts the same future for Kensington. In our opinion no future in store for Kensington could be worse than the present state. The old church is gone and in its stead is a Gothic building absolutely correct and as absolutely lifeless. The Terrace has been carted away and its site covered with monstrous shops, and the old High-street is being rapidly converted into a sort of Westbourne-grove. Remain only Kensington-square, the one or two old houses in Church-street, and, we trust, the unique South-end Buildings. Soho never suffered this degradation. She passed straight from being the home of wit and fashion to poverty and slumminess, but was never vulgarised. It is better to see a fine old house turned into a human rabbit-warren than for its place to be taken by a packing-case composed of walls, iron girders, plate-glass windows, and stuffed to the roof with "cheap lines," representing the very evils Mr. Sherwell complains of; for the lost house can never be replaced, while the rabbit warren may, by dint of care and good legislation, be made at least sanitary. Mr. Sherwell's figures on the state of overcrowding which obtains in Soho and in other parts of West London are simply appalling. Thus the percentage of the total population of persons living four or more to one room 10 in Soho and 4 in Kensington, compared with 3 in Bermondsey. Mr. Sherwell remarks that it would probably startle nine-tenths of the inhabitants of Kensington to know the amount of overcrowding in their sanitary area. We do not know how it may be now, but some seven years ago there were houses in Kensington which for dirt and poverty surpassed anything that could be seen in St. Luke's. This overcrowding is, of course, responsible for much of the misery and want in the district; but it is not to be wondered at when single rooms rarely let for less than 5*s.* or 6*s.* a week and three rooms from 14*s.* to 25*s.* a week, and this, too, when efforts have been made to remedy this defect by the erection of "models," but even these have not solved the problem of rent.

Comparing them with the Peabody Buildings we find:—

Soho.

Single rooms	6*s.*	per week.
Two small back rooms	7*s.* 6*d.*	,,
Three small back rooms	10*s.*	,,
Two front rooms	10*s.*	,,
Two front rooms and one back ...	16*s.*	,,

Peabody Buildings, Shadwell.

One room	2*s.* to 2*s.* 3*d.*	per week.
Two rooms	3*s.* 3*d.* to 3*s.* 6*d.*	,,
Three rooms	4*s.* 3*d.* to 4*s.* 6*d.*	,,

The results of overcrowding are well known—easy spread of infection, propagation of disease, and a high mortality, especially infantile, are among them. We may at present leave morality out of the question.

To take an example, the deaths per 1000 in 1894 from phthisis were: 3·2 in the Strand; 3·1 in St. Giles-in-the-Fields; 2·3 in St. George-in-the-East; 1·5 in Kensington; and 1·3 in St. George, Hanover-square.

Soho and neighbouring districts suffer, as, in fact, all large towns do, from the uncertain character of the work. During the season there is an enormous pressure of work, while from August to November nothing is done. Another unfortunate feature is the variety of trade carried on. The people are apparently a sort of industrial Ishmaelites; there is no cohesion, no pride in their work. There are, of course, dressmakers and tailors, but they work under conditions which make it impossible to be a good craftsman, and as for waiters, kitchen porters, supers, cab touts, and sandwich men, how can any of these work with any idea of the dignity of labour or feel that if a thing has to be done it is best to do it as well as possible? We have not space here to go into Mr. Sherwell's analysis of the tailoring trade in West London, with its appalling revelations, and we think he lays a little too much stress upon the follies, vices, and pleasures of wealthy West London. We cannot think that this is the major cause of the poverty of Soho. So complicated a problem is not easily solved. If more model buildings—not great barracks, but three- or four-storied buildings—were to be erected and properly managed, we believe they could be let at moderate rents, would soon be self-supporting and would go some way towards meeting the overcrowding difficulty. Lord Rowton has solved the problem and so, apparently, have the Peabody trustees. There is the Guinness Trust; and, to deal with miscellaneous monies, there were in 1894, according to Mr. Burdett, some £13,000,000 raised in Great Britain for charities. Of this sum £5,000,000 odd were received by London institutions. Surely it would be possible out of this pile of gold [and it must be remembered that in addition there is an enormous amount of charity which never finds its way into subscription lists, for the above figures do not include any money for so-called "Church work"] to arrange better times for workers, better houses, better homes, and happier lives. It is no good teaching Board School children physiology, or, indeed, anything, until they have decent homes and food. Mr. Sherwell does not offer

Hosted by Google

any solution of the problem he puts forth, but such a sombre picture has never been drawn since Mayhew's "London Labour and London Poor." The craftsman, poet, and worker who has so recently passed from us, managed to get good work done, to pay his men well, and not to lose money. If one man could do this it is not impossible that others may do likewise.

Eléments d'Ophtalmologie Journalière. (*Elements of Everyday Ophthalmology.*) Par les Drs. A. PUECH et C. FROMAGET, ex-Chefs de Clinique à la Faculté de Médecine de Bordeaux. Paris: Société d'Éditions Scientifiques, 4, Rue Antoine-Dubois. Pp. 246.

THIS is a compact little book giving a short but correct description of the chief affections of the eye with the simple treatment at the command of a practitioner who has not devoted himself especially to ophthalmic work; but the authors have wisely refrained from entering into any details of such surgical operations as are required for entropion, ectropion, strabismus, and the like, and although extraction of the lens in cases of cataract and iridectomy are described few would venture to operate with no more information than can be found in its pages. We are somewhat surprised to see jequirity recommended for pannus, since it is a remedy which, though it may be efficacious in practised hands and in a properly selected case, is yet liable to set up uncontrollable inflammation and would require more careful watching than is here suggested. The authors strongly recommend sub-conjunctival injections in cases of hypopyon-keratitis, using 1 part of sublimate and 2 parts of sodium chloride in 2000 of water. They state that they have had good results from large injections, but that they are apt to produce pain, chemosis, and considerable œdema of the eyelids, symptoms which would tend to shake the confidence of the patient in the surgeon, especially if he were young, and, therefore, should not have been mentioned here. In speaking of wound of the cornea with prolapse of the iris the use of eserin during the first few hours should have been mentioned if the prolapse is near the periphery of the iris. There are no illustrations, but the work, being reliable and written in short and clearly expressed sentences, might well be used as a primer for a student who wishes to learn to read an easy book in French.

At the Court of the Amîr. A Narrative. By JOHN ALFRED GRAY, M.B. Lond., late Surgeon to H.M. the Amîr of Afghanistan. London: Richard Bentley and Son. 1895.

AFGHANISTAN, apart from any question of politics, is an intensely interesting country and its present ruler a very remarkable man, so that any book dealing with life in that country is generally worth reading. Dr. Gray was, of course, on terms of great intimacy with the Amîr and saw a great many things which are hidden from the eyes of the casual traveller. Dr. Gray's first introduction to the hospital at Kabul was rather amusing. He found about eighty Afghans waiting to be cured by the "Feringhi doctor," and a guard with fixed bayonets had to stand at the door to keep back the crowd. This system might be introduced over here, perhaps, with advantage as a measure of hospital reform, and we are sure would meet with the approval of many an overworked house surgeon or house physician.

We might go on quoting all sorts of delightful stories from this book, but we have only space for one. It shows at once the best and worst traits of Oriental character, and makes the reader understand how it is that every foreigner who is brought into contact with the Amîr seems to feel a strong attachment for that very remarkable man. "His Highness had heard that I was ill and I told him that I had not with me the medicine I wished to take. His Highness asked, Would I take native medicine if he prescribed it? I said I should be most grateful to His Highness if he would honour me so far. His Highness gave some directions to a Hakim, who presently brought a small jar. The Amîr told me it contained a medicine he was himself taking. With a little silver spoon he took some dark-looking confection out of the jar, made a bolus of it, and gave it to me. It tasted hot and very nice. There was no more in the pot and he sent the Hakim away to make some fresh. It was then that my mind became troubled within me, for I knew the Hakim loved me not. Presently the jar was brought back, and as they were about to give it me His Highness asked for it. He scooped a little out with the spoon, and was raising it to his lips when the Hakim stopped him and whispered in his ear. The Amîr turned and looked at him, and the Hakim hurried away with a very red face. By-and-by he returned with the jar. Again the Amîr took it, and, looking at me, he raised a spoonful to his lips and swallowed it. He then gave the jar into the hands of the Armenian, who immediately brought it to me." It is needless to comment upon the courtesy and kindliness displayed by this act. Our readers will doubtless remember some articles by Dr. Gray, entitled "Afghan Physicians and Surgeons," which appeared in our columns during June, 1894. Several of the incidents therein mentioned have been incorporated in the book we now notice, and we have no hesitation in saying that all those who enjoyed the former articles will equally appreciate this book.

LIBRARY TABLE.

Sell's Dictionary of the World's Press. London: H. Sell, 1897. Price 7*s.* 6*d.*—This now well-known annual appears for the seventeenth time, and has been specially compiled to commemorate the sixtieth year of Her Majesty's reign. The new volume is appropriately styled the "British Empire Edition," and the front cover is embellished with a crowned portrait of the Queen. As is explained in the article "The Queen's Newspapers," the book professes to give "a complete and comprehensive account of the Fourth Estate throughout Her Majesty's vast dominions," and to enable this programme to be carried out the foreign section has been excised from this year's edition. The book contains several useful maps and diagrams and is embellished with some interesting portraits and autographs. The first part of the volume, which now extends to 1226 pages, comprises articles of interest, not only to Pressmen, but to every citizen who—as he should do—takes an interest in the Fourth Estate of the Realm. Many interesting and little known facts are given. For instance, few are aware that in the Press Gallery at Ottawa reporters change sides with changes of the Government just as members of parties do at home. "Leading Lady Journalists with Portraits" gives some idea of the invasion of the journalistic province by the fair sex. Part II. gives a complete list of newspapers, magazines, periodicals, &c., published throughout the British Empire.

JOURNALS AND REVIEWS.

Janus: Archives Internationales pour l'Histoire de la Médecine et pour la Géographie Médicale. (Janus: International Archives of Medical History and Geography.) London: Williams and Norgate. 1896. Price 20*s.* annual subscription.—We desire to call attention to this most interesting periodical issued in Holland, but obtainable in all parts of the world. It is of a strictly international character, the articles it contains being written either in French, German, or English. Issued at bi-monthly intervals, the first two numbers have now appeared, Professor Stockvis of Amsterdam leading off with an interesting article entitled "*Janus* Redivivus"; for it appears that this is not the first time that a journal of like name and purport has been published. Half a century

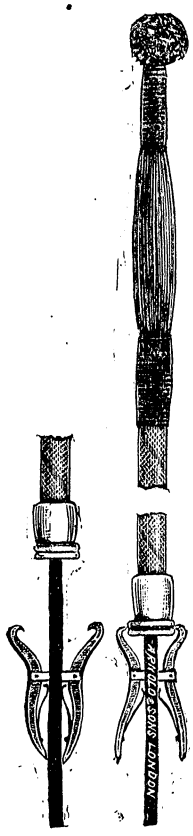
Hosted by Google

ago Dr. Henschel, Professor of Clinical Medicine at Breslau, conceived the idea of an international journal dealing with the history of medicine, and obtained the coöperation of some of the best scholars in different countries. He called the journal *Janus*, but it failed to receive the support it merited and ceased to exist after three years. It was revived in 1851 by Dr. Henschel in collaboration with Professor Heusinger, and this time was published at Gotha. This second venture did not, however, exist more than a few years. Professor Stockvis hopes that the new revival will meet with a better fate, and his wish will be echoed by many both in the New World and the Old who take an interest in the subjects with which the journal deals. Besides original articles each number contains bibliographical notices from all countries. Amongst the contributions are articles on Variolation and Vaccination, by Dr. J. Petersen of Copenhagen; an account of his second Visit to Iceland to Study Leprosy, by Dr. Ehlers; and a Study of the Cerebral Cortex and the Physical Substratum of the Mind, by Dr. Adamkiewicz of Vienna. Dr. A. Calmette writes on Snake-poison and Prophylactic Treatment of Snake-bite. An interesting paper (in English) is that of Dr. J. Carlson of Copenhagen upon the History of Diphtheria in Denmark. Dr. Peypers, the editor, reproduces the text of an essay on the Cause of Diseases, written in 1726 by an English physician, who is styled by Dr. Peypers a "pseudo-precursor of Pasteur." In the second number Dr. Fiessinger gives a curious account of the precautions against the contagion of plague adopted in the seventeenth century, illustrated by a quaint drawing of the mask and clothing worn by the medical attendant. An account of "Burnt Substances" taken from Alexander Trallianus is given by Dr. E. Trosse of Neuenahr; and a description of Epidemics of Ergotism in Russia, by Dr. A. Grünfeld. Altogether, *Janus* is a notable addition to periodical literature.

The third number of the *Journal of Experimental Medicine*, edited by Professor Welch of Baltimore and published by Messrs. D. Appleton and Co. of New York and London, fully keeps up the standard promised in the first two numbers. It contains ten articles dealing with Physiology, Pathology, Therapeutics, and Hygiene. The first article is by Messrs. J. J. Abel and Walter S. Davis on the Pigment of the Negro's Skin and Hair. They have been able to collect the pigmented granules of the negro's skin and hair and submit them to chemical examination. They consider that both pigments are identical and are probably the same as the pigment found in the hairs of the white races, the difference being merely one of quantity. In an article on Hæmorrhagic Cysts of the Thyroid Gland Dr. W. I. Bradley maintains that the gross cysts of the thyroid which possess fluid contents are essentially of hæmorrhagic origin. Dr. A. C. Abbott's paper on the Significance of Pathogenic Spirilla in American Surface Waters is of considerable interest. Dr. Abbott has gone very fully into the pathogenic action of a spirillum, not the cholera organism, found in American surface waters. The same author has a very interesting note on the Influence of Acute Alcoholism on the Normal Vital Resistance of Rabbits to Infection, from which he concludes that, with few exceptions, alcoholised animals are much more susceptible, and at an earlier date, to streptococcic inoculations than are non-alcoholised rabbits. Dr. Adler and Dr. Meltzer make an Experimental Contribution to the Study of the Path by which Fluids are carried from the Peritoneal Cavity into the Circulation, and Dr. Meltzer has a Note on Absorption of Strychnine and Hydrocyanic Acid from the Mucous Membrane of the Stomach. Dr. Beyer, in a paper on the Influence of Exercise on Growth, gives records taken from 605 cadets as a standard and compares them with records of 188 observations in a gymnasium, from which he finds that between the years of sixteen and twenty-one there is an average increase of weight in the cadets of 268 kilogrammes and in the gymnasts of 1176 kilogrammes, and he concludes that the "wonderful performance of most of our strong men are well within the reach of the majority of healthy men if such performances were a serious enough part of their ambition to make them do the exercises necessary to develop them." Dr. Mead Bolton and Dr. Herbert D. Pease have apparently fallen into the error of assuming that the fluid developed in electrolysed toxin is a true antitoxin and not Hermite fluid. Dr. Mead Bolton also has a note on the Presence of Antitoxin in Horses that have not been Treated by Diphtheria Toxin in which he finds one-thirtieth of a normal antitoxin unit. Dr. Simon Flexner contributes an interesting study of Terminal Infections which is well worthy of careful reading.

The Scottish Medical and Surgical Journal.—The first number of this new monthly is an excellent beginning, and the list of contributors who have promised literary support is almost a guarantee that a high standard will be maintained. In one of our previous allusions to its forthcoming appearance attention was directed to the fact that the profession in Glasgow was inadequately represented in an undertaking which aimed at being comprehensively Scottish; but this defect has now been satisfactorily remedied. The original articles are eight in number. Professor Stephenson of Aberdeen discusses the Management of Labour in Twin Pregnancies, and concludes that it is safer for the mother and the second child that the labour should be ended as soon as possible, and that in head presentations of the second child it is preferable to turn at once than to incur the risks of delay and the necessity of using forceps. Dr. Clouston of the Royal Edinburgh Asylum writes on Cortical Stimuli. Dr. A. Ballantyne, President of the Edinburgh Obstetrical Society, has a long paper on the Use of Chloroform in Midwifery Practice. Dr. Alexander James of Edinburgh describes a case of Rickets beginning at the age of seventeen years; this paper is accompanied by illustrations reproduced from ordinary and Roentgen photographs. Dr. J. Crawford Renton of Glasgow gives an account of four cases of Sciatica in which exposure of the nerves and removal of adhesions were followed by recovery. Mr. D. M. Greig of Dundee describes a case of Complete Extirpation of the Gall-bladder, with removal of part of the liver; the patient regained good health and could attend to her usual household duties. Dr. Alexander Bruce of Edinburgh has an illustrated paper on a special tract in the Limiting Layer of the Spinal Cord. Dr. David Newman of Glasgow gives details of five cases of Disease of the Kidney which required operative treatment, but presented difficulties in diagnosis. There is also a "Digest" by Dr. George Dean of Aberdeen on the Serum Diagnosis of Disease. Reports of the meetings of societies in Edinburgh, Glasgow, Aberdeen, and Dundee, reviews, abstracts from recent literature, and a section on Scottish medical news fill up the remainder of the ninety-six pages. The editor is Dr. William Russell, assistant physician to the Royal Infirmary, Edinburgh. The publisher is Mr. W. F. Clay, 18, Teviot-place, Edinburgh, whose London agent is Mr. Henry Kimpton. The annual subscription is one guinea.

The Practitioner.—The opening paper is by Mr. Butlin on Sarcoma of the Lower End of the Femur and is illustrated by skiagraphs as well as by an engraving of a longitudinal section. Dr. Patrick Manson describes recent investigations on Bubonic Plague. Dr. John Macintyre of Glasgow has an elaborate article on the Use of the X Rays in Diseases of the Nose, Throat, and Thorax. By large focus tubes and powerful coils he has "succeeded in sending the rays 16 ft. across a room, then through a thick door into the next chamber, and this in sufficient force to show the contents of



Hosted by Google

a surgical case on the fluorescent screen." For examination of the structures of the nose, throat, &c. he employs fluorescent screens in the form of a tongue depressor put into the mouth. The "Hero of Medicine" this month is Ephraim McDowell of Virginia, the "Father of Ovariotomy"; he performed the operation in December, 1809, and the patient survived for thirty-two years.

New Inventions.

AN IMPROVED ŒSOPHAGEAL PROBANG.

THE extraction of foreign bodies which have become impacted in the œsophagus is an operation frequently required, and one for the performance of which many expedients have been devised. Fragments of bone hastily swallowed at meal times are perhaps the most usual examples of this kind of accident; artificial teeth sometimes also lose their hold and slip down the throat, children swallow portions of their toys, and coins, pins, nails, &c., held between the lips not infrequently disappear in the same way. In many cases these foreign bodies may be caught and pulled out by means of the ordinary œsophageal probang, tipped with a piece of sponge and with an expanding ring of bristles. This instrument, however, is somewhat difficult to pass down into the œsophagus because it must be held by the outer tube, and the sponge-end being pressed back by coming in contact with the back of the throat causes the ring of bristles to open out and thereby impede its entrance into the gullet. To obviate this Messrs. Arnold and Son, London, at my suggestion, have fastened a clip on to the free end of the whalebone to catch the bone end of the catheter, the outer tube. This holds perfectly fast while the probang is being passed, and directly it has gone far enough the finger and thumb open the clip and withdraw the probang with its ring of bristles expanded.

E. MANSEL SYMPSON, M.D., B.C. Cantab., M.R.C.S. Eng.,
Surgeon to the Lincoln County Hospital.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5.30 P.M. on Dec. 30th, 1896, at 25, Grosvenor-street. In the unavoidable absence of the President, Mr. George Pollock, Mr. F. J. Gant took the chair.

The minutes of the preceding meeting were read and confirmed.

Mr. H. P. Dunn, the honorary secretary, reported that owing to various causes it had not been possible to arrange for the holding of the annual general meeting of the association, and at the same time pointed out that it would be expedient to call a general meeting of the association at an early date in the New Year. This suggestion was accepted by the committee and the settlement of the exact date was left for subsequent determination. The question of raising the subscription of the association from 2*s.* 6*d.*, as at present, to 5*s.* was then discussed. Various opinions were expressed upon the subject and the general view was in favour of the change. It was ultimately agreed to submit the matter to the annual general meeting for decision.

In accordance with the resolution passed at the last meeting of the committee the honorary secretary read a special address drawn up by a sub-committee for circulation among the Fellows of the College, inviting them to join the association and to take an active part in forwarding its objects.[1] The report was approved and unanimously accepted. Mr. R. B. Anderson, one of the honorary secretaries to Mr. Rivington's election committee, brought up a report to the Association of Fellows of the Royal College of Surgeons of England, on behalf of the representatives of the association, on Mr. Rivington's election committee. The report was approved and adopted.

Mr. Rivington reported that in accordance with the request of the committee conveyed to him at the last meeting he had given notice to the secretary of the College that he would move the resolution in favour of a grant from the Council to the appeal of the Privy Council on behalf of Mr. R. B. Anderson and had received an acknowledgement from the secretary.

Mr. Rivington then called the attention of the committee to the fact that no report of the proceedings of the association had been issued since 1892, and expressed his opinion that it would be very desirable to bring the account of those proceedings up to date and issue a copy of the report to members and others, more especially as there was some prospect of the subscription to the association being raised. He then moved the following resolution, which was seconded by Dr. Barnes and carried unanimously:—

"That a sub-committee consisting of the president, two vice-presidents, and honorary secretary, be appointed to draw up a report of the proceedings of the association from the date of the last report to the present time for transmission to the members of the association."

This concluded the business of the meeting, and the committee adjourned.

[1] The address will be found printed in full at page 126 of our present issue.

PRESENTATIONS TO MEDICAL MEN.—At a meeting held on the 21st ult., in the District Hospital, West Bromwich, Dr. A. P. Steavenson, until recently senior house surgeon to that institution, was presented by the honorary secretary, on behalf of the patients and officials, with a valuable case of surgical instruments.—Dr. R. W. Lethbridge has been the recipient of a handsome testimonial on his departure from Alexandria, Victoria, Australia.—On the 23rd ult., at a meeting in the Council Chamber at Luton, Mr. W. R. Phillips, J.P. (vice-president of the Bute Hospital), in the chair, Dr. David Thomson, on the occasion of his leaving the town, after many years' residence there, and specially in recognition of the great work he had done for the Cottage Hospital during eighteen and a half years, was presented by Mr. W. R. Phillips, on behalf of the subscribers, with a handsome gold keyless chronometer, which was thus inscribed: "Dr. David Thomson.—In remembrance of generous service at Bute Hospital, Luton, and other good work. December, 1896."—Presentations have been made to the following gentlemen, in acknowledgement of gratuitous instructions on First Aid—namely, to Mr. J. K. Goodall, L.R.C.P., L.R.C.S. Edin., of Brimington, a silver-mounted walking stick, from the members of the Midland Ambulance Class at Whittington; to Mr. W. Crooke, L.R.C.P. Lond., M.R.C.S. Eng., of Egremont, a beautifully inscribed barometer from the Ambulance Class in connexion with the Seacombe Technical Institute; to Dr. Llewellyn A. Morgan of Liverpool, a handsome teapot from the members of the Ambulance Class, recently organised, at the Central Station of Ambulance Work on the Cheshire Railway Lines; and to Dr. W. George Willoughby of Eastbourne a malacca cane walking stick, with ivory handle, and a silver band bearing the inscription, "Presented to Dr. Willoughby by the Eastbourne Borough Police Ambulance Class. 23rd Dec., 1896."

THE LANCET.

LONDON: SATURDAY, JANUARY 9, 1897.

THE elevation of Sir JOSEPH LISTER to the Peerage is an event to be regarded with unqualified satisfaction. Nothing is more noticeable than the universal approval which it has called forth from all quarters. The press of every party and shade of political feeling has been hearty in its praise of the creation of the new peer and so far from regretting the departure has pleaded for an even wider recognition of the claims of medicine. The fact is a very significant one and will go far to encourage our statesmen to be less timid in extending, or rather in using, the Royal prerogative to create peers at pleasure—a prerogative which has never been disputed. Though the unanimity of the press and of all parties in this matter is very gratifying it is satisfactory to notice that the new departure has been taken by a Conservative Minister—or, to speak more accurately, by the Conservative head of a Unionist Ministry. When the party taking such a step forwards is one which is supposed to stand on ancient ways, and one most apt to see the difficulties and the objections to innovations, there is the more assurance that the advance will not be retraced, but that with favouring circumstances it will be succeeded by others in the same direction. HER MAJESTY'S appreciation of the services which medicine has rendered to humanity is well known. Her loyal and constant confidence in those distinguished members of the profession by whom she has been faithfully served has been an example to the public. In the many anxious times of her history when she, and her people in sympathy with her, have been awaiting the issues of life and death she has ever known how to support her medical advisers by her trust and to reward them with her favour. We are quite sure, therefore, that when her responsible Ministers came to be of opinion that medicine should be honoured by a representative in the House of Lords they found no difficulty in getting HER MAJESTY'S gracious consent. That such a proposal should have been made by the Marquis of SALISBURY will enhance the satisfaction of Sir JOSEPH LISTER. His Lordship is not only at the head of a powerful Ministry, but his knowledge of science, and the fact that he has himself been President of the British Association for the Advancement of Science, increase the value and significance of a medical peerage granted upon his recommendation. Sir JOSEPH LISTER may well dwell on the fact of his progression in honours and the division of the credit of them between the two most conspicuous statesmen of the country. It was Mr. GLADSTONE who, under HER MAJESTY'S authority, conveyed to Sir JOSEPH LISTER the intimation of his baronetcy, and who did so with every expression of personal satisfaction. And now it is the Marquis of SALISBURY who, in full sympathy with the public opinion of Sir JOSEPH LISTER'S merits and his world-wide fame, calls him into that branch of the Legislature where his rare knowledge and foresight may serve to guide legislation in ways of safety on questions deeply affecting the health and happiness of the empire.

We have treated this action on the part of Lord SALISBURY and his Ministry so far from a purely public point of view, conceiving the admission of members of the medical profession into the House of Lords as an obvious advantage to the public and the House. There is a deep faith in the Second Chamber, which faith will be strengthened by the addition of men of commanding character and wisdom, who have not been called to it by the accident of birth. To Sir JOSEPH LISTER himself this elevation will bring strange associations and varied thoughts. He is too deeply absorbed in the great problems of modern medicine, which excite hopes beyond the dreams of our immediate predecessors, to be spoiled or dazzled with the conventional grandeur of his new position. But he may well be trusted to appreciate the honour to him and to his profession which it implies, as well as the responsibility. We do not expect him to develop any new ardour in party politics or even to hear of his frequent participation in debate. But for all that we expect him to be a power on occasion in defence and furtherance of the health and happiness of the people and, if need be, of the profession of which he is a most distinguished leader and ornament. To that profession at large the event is very pleasing. Had a *plébiscite* of all British medical men been taken for the nomination of one man the vote must have been unanimous in favour of Sir JOSEPH LISTER. He was one of the most careful of surgeons and one of the most successful. Whether his patient was a hospital patient or a private patient he had the same care for him. But beyond his solicitude for individual patients he was ever the scientific seeker after those truths the bringing to light of which resulted in the establishment of the antiseptic treatment, with its splendid results. For thirty years at least he has unceasingly pursued this end with a result in the saving of life comparable only to that effected by EDWARD JENNER.

In conclusion, we have only to say that our own gratification is complete. For years we have urged this step on successive Ministries as eminently indicated by the wants of the public and the importance of the profession. Very lately we even ventured to suggest both the step which Lord SALISBURY has so happily taken and the individual name which he has selected. We have waited long to see the realisation of our wishes and have been conscious sometimes of almost impatience; but this is not the time to complain. Lord SALISBURY has, indeed, made this year a notable one for medicine and infused fresh encouragement into the hearts of those who pursue it, and he will long enjoy the gratitude of the profession for a new and truly statesmanlike departure.

RATHER more than ten years ago[1] we drew the attention of readers of THE LANCET to the importance which thrust

[1] THE LANCET, July 17th, 1886, p. 143.

Hosted by Google

wounds of the orbit possess from the very great fatality which follows their infliction. The extreme thinness of the bones forming the roof and inner wall of the orbit makes penetration of the cranial cavity by a slight thrust from an umbrella, walking-stick, foil, pipe-stem, &c., easy of attainment, whilst the elasticity of the skin and orbital contents causes the wound of entrance to appear of far less consequence than it really is. We can find excuses for the surgeon of bygone days, who was chiefly dependent on the few cases of surgical interest which could be seen when walking the hospital of the period for the experience which was to guide him in future life and who could obtain but limited information from books. To-day the conditions of professional training and practice are quite changed. For years the medical press has been accumulating cases of the rarer diseases and injuries until almost all that can be known about them has been placed before the profession. At intervals we have considered it advisable to make a *résumé* of our knowledge on some subject and take thought of our position with regard to it. As regards the subject of which we are writing now no advance has, in our opinion, been made during the time which has passed since we last drew the attention of our readers to it. When investigating the subject a few years ago[2] we found the mortality from these injuries to be over 90 per cent., and we think this excessive mortality to be the result of the policy of non-intervention which was formerly the bane of abdominal surgery. If the surgeon is aware, as he should be, of the dangerous character of wounds inflicted by thrusts of the kind under consideration, harmless though they appear, he has no excuse for not treating the case in the same manner as he would treat a punctured fracture of any other part of the cranium with probable injury to the brain. Careful examination of the wound must be made, the track rendered as far as possible aseptic, foreign bodies and bone splinters removed, and adequate provision made for drainage. This need not involve the loss of the eye unless that organ has been irreparably injured by the instrument which caused the damage. Nor need the scar which must result from the operation cause much disfigurement; this must not, however, be allowed to weigh with the surgeon in the face of the great danger to life. "Waiting for symptoms" cannot be too strongly condemned in the light of our present knowledge; this course, which is so much the easier in the presence of a wound which is apparently of trifling extent, is almost invariably a fatal one. Sometimes, however, brain substance escapes from the wound and there is no doubt that the brain has been penetrated and severely injured. The indication is then clear, but not always followed. We know of two or three cases of thrust wound of the orbit which have been recently under treatment in hospitals in which it was decided to wait for symptoms; all proved fatal. As the late Mr. HULKE[3] wrote some years ago of the course of events after such injuries: "Of brain symptoms there may be none. Two or three days may pass over, during which the patient goes about as usual; then brain symptoms make their appearance, sometimes suddenly, and the patient dies in the course of a few hours or days, and the true nature of the case is revealed only by the post-mortem examination." The portion of brain usually injured is not very important in the carrying on of the ordinary cerebral functions, and the inflammatory mischief may be too extensive for repair when the symptoms which are supposed to justify interference are first noted; the surgeon may not find the abscess should there be one (as in a recently published case); or the fatal event may supervene too rapidly although the symptoms are delayed for a week. The cases of recovery to which we have access are not very numerous. Sir PRESCOTT HEWETT,[4] in his lectures on injuries to the head, mentioned two. The first was that of a boy aged four years who fell with a cheese knife in his hand. The point of the knife entered the orbit, and on its withdrawal, which required force, brain substance followed. He recovered and was well seventeen years afterwards. The second case is taken from MORGANI. A young man received a punctured wound in the left orbit, became paralysed on the same side, and had fits on the opposite side with aphasia and delirium. He then complained of pain in the right ear, and in three weeks there was discharge from the ear; after the cessation of the discharge he recovered. LAPLACE[5] had under his care a man who received the end of a foil in the left orbit. Coma with paralysis of the right side of the body and left side of the face rapidly ensued. The pulse rose to 140 and the temperature to 104·5°. On the fourteenth day the left temporal region was trephined; the dura mater was found to be congested; a platinum wire was passed to the cavernous sinus and about a drachm of blood clot removed. The trephine opening was plugged, and a tight bandage applied. He recovered, but with some anæsthesia around the orbit and internal squint. It was supposed that the foil had entered the sphenoidal fissure. HULKE[6] had a patient aged thirty-six years under his care, with the vulcanite mouth-piece of a pipe embedded in the orbit, who recovered; but it is not certain that the dura mater was wounded. BEAUMONT'S[7] case is historical. A man who was watching the firing of a rocket felt a sudden blow in the left eye. A piece of wood five and a half inches long, the transverse section of which was four-tenths of a square inch, was extracted with difficulty. A profuse gush of blood followed, but was arrested with the application of iced water. He suffered severe headache and vomiting for the first twenty-four hours, but was not rendered unconscious. He lost vision in the eye on that side and had anæsthesia in parts supplied by the infra-orbital nerve. Three years afterwards he was in good health, but had an impaired memory. Mr. A. F. HAWKINS[8] removed a piece of broken knitting-needle nearly three inches in length from the orbit of a child three years of age who had fallen on it. The child appeared somewhat dazed for a moment, but went on with her work. On the fourth morning there was paralysis of the left side, more marked in the upper than in the lower extremity. The end of the needle was about three-quarters of an inch from the puncture in the

Hosted by Google

skin. The paralysis continued for ten days after removal of the needle, then began to subside, and afterwards rapidly passed off. She was quite well a year later. Mr. GODLEE and Dr. POPE[9] had a patient under their care who had received a stab from the point of an umbrella in the left orbit. Much shock and vomiting followed. Later he had aphasia, epileptiform seizures, paralysis of the right side of the face and tongue, and somewhat irregular temperature. He recovered. A horse-hair drain was placed in the wound about the third day and replaced by a small drainage-tube on the eighth day, which was shortened on the thirteenth. The wound was twice explored and the question of trephining considered. POLAILLON'S[10] case was that of a boy aged eighteen years who had the point of an umbrella thrust through the roof of the orbit. He was found in a state of coma; the foreign body had been removed with difficulty. An incision was made in the forehead and a portion of the frontal bone chiselled away; the dura mater was incised and some blood and cerebro-spinal fluid escaped; five splinters and a portion of damaged brain-substance were removed and a small artery tied with catgut; the débris of the eyeball was enucleated and a drain passed from the frontal wound through into the orbit. The patient became conscious in a few hours and had no bad symptoms afterwards. Healing took place well and quickly. In THE LANCET of Jan. 2nd, p. 38, will be found the account of a case under the care of Mr. A. WINKFIELD, where the wound was carefully drained at first, and on the occurrence of symptoms at a later date trephining was resorted to with much benefit. HULM'S[11] statistics on the subject show the diminished mortality which follows surgical interference in all cases of foreign bodies in the brain when the surgeon operates at the present day and observes modern precautions.

THE increase of longevity is one of the main objects of all work in the field of preventive medicine, and the question "Is longevity increasing?" is only another form of the still more pertinent question—"Has the recent development of preventive medicine yielded any tangible results on the duration of human life?" At this season of the year industrious paragraphists in some of our lay contemporaries often exercise their ingenuity by tabulating the ages of persons whose deaths were announced in their obituary columns during the recently completed year. It may be interesting to some of the readers of a newspaper to learn, for instance, that during 1896 its obituary columns contained notices of 7743 deaths, 1141, or nearly 15 per cent., of which were of persons aged upwards of eighty years, and that 165 were deaths of nonagenarians. It is scarcely necessary, however, to point out the absolute futility of this class of statistics, even when we are further told the proportion of the announced deaths of octogenarians in a given newspaper in a series of years. A high proportion of deaths of aged persons may be due to the epidemic prevalence of influenza, or be the result of exceptionally severe weather, but this would not prevent this class of statistician from claiming it as evidence of so-called "longevity."

If we would seek an answer to the question "Is longevity increasing"? we must consult a very different class of statistics. The series of Life Tables published by the Registrar-General during the last fifty years clearly prove that the mean duration of life in England is steadily increasing and that this increase is an increasing rate of increase. During the thirty years 1841–70 the English death-rate was practically stationary at 22 per 1000; in other words, preventive medicine was only able in that period to counteract the deleterious effect of the constantly increasing aggregation to towns. Under the stimulating sanitary influence of the Public Health Acts of 1872 and 1875 the national death-rate fell in 1871–80 to 21 per 1000 and further to 19 per 1000 in the decennium 1881–90. The effect of this marked decline in the English death-rate is clearly shown by the three principal Life Tables published by the Registrar-General. For instance, the mean duration of the life of males, according to Dr. FARR'S Life Table, based upon the mortality statistics of the seventeen years 1838–54, was forty years; according to Dr. OGLE'S Table, based upon the ten years 1871–80, it had increased to forty-one years; and by Dr. TATHAM'S Table, based upon the more recent decennium 1881–90, it had further increased to nearly forty-four years. Thus the mean duration of life among males has increased under the influence of preventive medicine by four years during the past fifty years. The increase of longevity among females has been still greater. Thus the mean duration of life of females, which was not quite forty-two years by Dr. FARR'S Table, rose to nearly forty-five years by Dr. OGLE'S Table and to forty-seven years by Dr. TATHAM'S Table, showing a total increase of five years in the same period.

Some are inclined to depreciate the value of this increase of the mean duration of life in England in recent years, because it is mainly due to the reduction of mortality in childhood. It is indeed true that after middle life the expectation of life has not increased, and has, indeed, slightly declined. The effect of this is, however, far more than counterbalanced by the largely increased proportions of persons who survive childhood and reach middle life. Thus, as has been pointed out, there has been a very considerable increase in the proportional number of years lived by succeeding generations between the most useful age-period of from twenty to sixty years. This may clearly be claimed as one of the results of the labours of preventive medicine. It remains to be seen whether further sanitary progress will make it possible to entirely counteract the effect of the increasing intensity of competition and the struggle for existence and survival which undoubtedly are now depressing the expectation of life after middle age. If, therefore, longevity signifies mean duration of life there can be no doubt about its increase in England in recent years. If, however, by longevity is meant the chance of middle-aged persons reaching extreme old age, English Life Tables do not supply so satisfactory an answer to our question.

So far back as Oct. 17th, 1885, we referred in an annotation headed "A New Objection to taking Oath," to the possible risk of infection from kissing the Book when taking the oath in a court of law. Allusion was made in that

annotation to the circumstance that a medical man, Mr. STRATHEM of Middlesbrough, on being summoned to give evidence in a case of drunkenness objected to swear on the Testament, not for the ordinary reason, but on account of the risk of infection. The objection astounded the legal authorities, who ruled that it was not a conscientious objection within the meaning of the Act. The witness at length swore under protest. Remarking on these facts it was observed at the time that "it must be allowed that there is something in the objection." In the following year we published a letter from Dr. HARKNESS of Derby complaining that when giving evidence in the Divorce Court he had been required to kiss the same book which had just previously been handled and kissed by two common prostitutes. His objection to do so on the very possible, not to say probable, grounds of infection afforded much amusement to the late Mr. Justice BUTT and some members of the Bar present, while other members supported the witness in his very reasonable objection. Ultimately, at the suggestion of the learned judge, Dr. HARKNESS kissed the open Book, though, as he urged in his letter, this did not prevent his handling an unclean thing. Many more letters, annotations, and articles too numerous even to summarise followed, and then the Oaths Act, better known, perhaps, as Bradlaugh's Act, was passed. This Act, as is well known, relieved all persons who, like its author, had no religious belief from taking an oath, permitting an affirmation instead of it. It continued to relieve also from the necessity of taking an oath those to whose religious belief it was contrary. It also contained a section (the fifth) which has already become memorable and promises to become more so. This section permitted any person to whom an oath is administered who desired to do so to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland. When this section became known to us, we used every effort to make it known to our readers and to induce them to take advantage of it. Here a serious difficulty occurred. Though the Act had for some time become law its fifth section was wholly unknown to many of those whose duty it wa to have had it at their fingers' ends—legal coroners, stipendiary magistrates, judges of county courts, recorders, registrars, and magistrates' clerks. Medical witnesses on claiming their rights under this section were treated not only illegally by being asked questions clearly contrary to the words of the section, but were also treated with rudeness and incivility. Indeed, such was the prevailing ignorance that Mr. ASQUITH, then Home Secretary, was moved to issue a circular to all coroners' and magistrates' clerks, calling their attention to the section and its provisions. Even this did not prevent some magistrates from acting illegally, as duly recorded in our pages. Fortunately a change for the better is at hand. The *Times* in its issue of last Saturday published a letter from Mr. FRANCIS A. STRINGER, of the High Court of Justice, author of "Oaths and Affirmations," and an undoubted authority in all that relates to the oath. In this letter he, with a courage and boldness much to his credit, condemns the English form of oath as liable to spread syphilis. He gives the forms in use in France, Belgium, Austria, Spain, and Italy and shows that kissing the Book is unknown in any of these countries. He also shows that the Scotch form, like the French, is much more solemn than the English one, and that though anyone may take it, not one witness in a thousand knows of the existence of the section of the Act which permits it. Consequently the uncleanly English oath remains in general use, for unless a witness asks to be sworn in the Scotch form the usher has no choice but to administer the usual English one. Mr. STRINGER concludes a most able letter by suggesting the bringing in a Bill to provide a short simple form of oath similar to that of Scotland and so making it uniform in the United Kingdom. The *Times* of Monday had an excellent leading article supporting Mr. STRINGER'S views and condemning the English form of oath on all grounds. What will, we trust, prove to be the beginning of a most interesting correspondence has commenced in the columns of our contemporary, and will, it is to be hoped, aid in the reform for which we have so long contended.

Annotations.

"Ne quid nimis."

NEW YEAR HONOURS TO THE MEDICAL PROFESSION.

THE New Year has brought to the medical profession, in the person of Sir Joseph Lister, the honour of a peerage. This is a departure in the bestowal of titles which all will welcome—and welcome not only because of the spirit which has suggested the offer of nobility to Sir Joseph Lister, but because of the undoubted deserts of the recipient. We make further reference to this grateful topic in a leading article. Dr. Richard Douglas Powell has received the honour of a baronetcy. Dr. Powell has for many years been a leader in the profession. He is physician to the Middlesex Hospital, consulting physician to the Brompton Hospital, and author of an excellent book on pulmonary disease. He is Senior Physician Extraordinary to Her Majesty the Queen and his well-merited title was expected for him by all his friends. Mr. William Raymond Kynsey, C.M.G., receives the honour of a knighthood. The Hon. Sir William Raymond Kynsey, a retired surgeon-captain in the army, is a member of the Legislative Council of Ceylon and Inspector-General of Hospitals and Asylums in the island. Deputy-Surgeon-General Charles Benjamin Mosse, C.B., receives a Companionship of the Order of St. Michael and St. George. The new C.M.G. is the superintending medical officer of Jamaica.

THE FIGURES OF THE MEDICAL PROFESSION.

THE Medical Directory for 1897 shows the numbers of the profession to have again increased, as they have done steadily for the last decade. This time the number of names included is greater by 958 than it was last year, the increase being the largest but one that has ever occurred in the course of one year. The exception occurred in 1894, when the number of practitioners was greater by 1062 than the number in 1893. The increase is fairly distributed between town and country and between the respective countries of the United Kingdom. The London list has gone up from 5835 to 5992; the provincial list for England from 14,702 to 15,081; the list for Wales from 1028 to 1062; the list for Scotland from 3264 to 3369; and the

THE LANCET RELIEF FUND.

For Members of the Medical Profession and their Widows and Orphans when in Distress.

——:o:——

ALMONERS.

THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.
THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.
THE PRESIDENT OF THE GENERAL MEDICAL COUNCIL.
THOMAS WAKLEY, F.R.C.S. Eng.
THOMAS WAKLEY, Jun., L.R.C.P. Lond.

HON. AUDITOR.

SIR HENRY PITMAN, M.D. Camb., F.R.C.P.

——:o:——

THIS FUND will be provided year by year in the month of January to the amount of at least £300 solely by the Proprietors of THE LANCET, and administered free of cost, for the purpose of affording immediate pecuniary assistance to Medical Men, or their Widows and Orphans, *in cases of Distress and Emergency*, by the grant of money by way of loans free of interest, or gifts, as the circumstances of the various cases may require.

Applicants must satisfy the Almoners of the Fund that they are qualified under the following regulation:—

* "The recipients shall be such persons as satisfy the Almoners that they possess one or other of the following qualifications—that is to say: (*a*) That the applicant holds a registered medical qualification, and that he has fallen into pressing need of immediate pecuniary relief; or (*b*) That they are persons who have been, previously to the date of application, legitimately dependent upon some person holding a registered medical qualification, and that they have pressing need of immediate pecuniary relief."

To ensure the utmost despatch, the "Application Form" upon the other side should be filled up and forwarded (in an envelope superscribed "THE LANCET Relief Fund") to the Secretary, Mr. EDWARD DAVIES, THE LANCET Offices, Strand, London, W.C.

The application should be accompanied by two separate testimonials, one from the Clergyman of the Parish or other resident Minister of religion, and one from a registered Medical Practitioner, stating—that the application addressed to the Almoners has been read, how long they have known the applicant, and that they believe the statement to be perfectly truthful, and such as may be acted upon without further inquiry.

Private and Confidential. *No.* .....

APPLICATION FORM.

To the Almoners of the Lancet Relief Fund.

The applicant should here state shortly:—

1. The nature of the emergency that has arisen.

2. The circumstances out of which it has arisen.

3. The amount of the grant desired, and whether by way of loan (free of interest) or of gift.

4. If by way of loan, state when the loan will be repaid; and from what source the funds to repay it are expected to be forthcoming.

Hosted by Google

5. Whether the applicant is entitled or able in the circumstances which have arisen to look to any other source of assistance and if so, what is the expected nature and extent of such assistance.

6. Whether the applicant is receiving, or has received during the past six months, pecuniary aid from any Medical Charity.

7. State how the applicant is qualified to receive assistance; vide regulation* on first page.

8. Particulars of:

Applicant's age

Number in family

How many are self-supporting

How many are partially dependent

How many wholly dependent

list for Ireland from 2563 to 2598. There are in the 1897 list 3652 names of registered practitioners resident abroad, as against 3453 names in the 1896 list; and 2510 names of officers in the Naval, Military, and Indian Medical services as against 2451. The totals, 20 being added to the present year and 24 to the past year under the heading "Too Late List" are as follows: 1896, 33,326; 1897, 34,284. The following averages are not calculated out to decimals. In the English provinces there is 1 medical man to every 1700 of the population. In London the proportion of medical men is about double as high. In Liverpool and Manchester, on the other hand, there is 1 medical man to every 1200 of the population, and this proportion prevails for the whole of Scotland. In Edinburgh, however, the proportion rises to 1 medical man to 500 of the population, while Glasgow, like London, possesses 1 medical man to every 850 or so of its laymen. In Ireland there is 1 medical man to every 1800 of the population, the medical men in Dublin amounting to about 1 in 600 of the population. In Wales there is 1 medical man to every 1500 of the population. The Directory is, as usual, an admirably edited and invaluable book of reference, doing credit to its well-known publishers, Messrs. J. and A. Churchill.

ARMY EXAMINATIONS.

WITH the exception of an occasional, and all too rare, promotion from the ranks the commissioned officers of the Army are selected by competitive examination in a great number of more or less abstruse subjects, and according to recent writers in the daily and weekly press—notably the *Broad Arrow* and the *Morning Post*—the consequence has been the alarming evolution of the crammer. The general tenor of the correspondence is unfavourable to the existing system. Most of the writers over such signatures as "A Retired Officer," "A Father of a Family," and so forth, contend that the brains of the candidates are unduly stimulated at the expense of their bodies, the result being a parcel of etiolated doctrinaires, admirable possibly as theorisers, but totally unfitted for the duty of leading men in action and controlling them in time of peace. "If there must be competition for the Army, as there is in every other profession," says the writer of a forcible letter in the *Morning Post*, "let it be in professional subjects as is the case in every other calling. First, let the lads who choose the army as a profession have the all-round education of gentlemen at their backs, including running, jumping, cricket, football, and all the English sports which are compulsory so long as they remain at school. Appeal to the colonels of regiments, to the parents of boys at school, to the public school masters, and to the boys themselves, and you will quickly ascertain which they would vote for, school and discipline or cramming, London music-halls, seaside watering-places, cigarettes, and late hours." There is much food for reflection in the above extract, and, indeed, the whole letter is worthy of the attention of the Civil Service Commissioners. The alleged enormous expense of the cramming process is another fruitful source of complaint, and that it must in reality be unduly expensive the lavish use of the advertising columns in many of our contemporaries goes far to prove. When the purchase system was abolished the idea was to throw open the army to all educated and well-behaved young men, whether they were possessed of means or not, but apparently the cost of a commission is indirectly just as prohibitive now as ever it was. Hundreds of fine, able-bodied youths, full of military aspirations and admirably constituted by nature for the exercise of command, are said to be rejected because their friends cannot afford the costly preparation necessary to ensure success, among them being many scions of military families, who are thus debarred from following in their fathers' footsteps. These in every respect unexceptionable candidates fail to score as many marks as their crammed competitors, but, on the other hand, the latter obtain credit for subjects which they have in no wise mastered. Thanks to the skill of their instructors, these forced pupils are enabled to retain temporarily in their memories a certain number of formulæ and answers to probable questions, but no sooner is the ordeal surmounted than at once their ephemeral learning begins to evaporate. From a purely sanitary point of view there is not a good word to be said for the system of cramming. A brain, like a stomach, requires food, but it must be judiciously administered in moderate quantity and at suitable intervals. A *pot-pourri* of indigestible matter poured well-nigh continuously into an immature brain, even during a period measurable by weeks, cannot possibly be assimilated, and must inevitably exercise an injurious effect on the over-stimulated organ. An officer above all things should be endowed with unfailing endurance, so that he may continue to lead and direct his men to the last. A system of education which over-stimulates the brain while neglecting the still unformed body can only be characterised as intrinsically bad. In this connexion it is impossible to improve on the concluding sentence of the letter from which we have quoted: "Let the qualifications be ample; only do leave our boys at school till they are grown up."

THE DANGERS OF ARTIFICIAL TEETH.

ON Dec. 28th an inquest was held at St. Bartholomew's Hospital with reference to the death of a patient from hæmorrhage caused by an artificial denture which had been swallowed some eight or nine months previously during a fainting fit. The patient was at the time seen by a medical man who, being unable to remove the denture by the mouth, forced it down towards the stomach presumably with the hope that it would be passed per rectum. Death from swallowing artificial teeth is more common than is generally supposed, and many cases are to be found recorded in the various journals devoted to dental practice. Artificial teeth properly fitted and secured are in themselves quite free from danger, and it is only when people persist in wearing small, loosely fitting dentures that trouble is likely to arise, as a fit of coughing or fainting or even drinking may dislodge them and so allow them to be swallowed. Should such an accident occur prompt treatment is necessary and if it is found impossible to remove the denture by the mouth or it fails to pass per rectum œsophagotomy or gastrostomy should be performed, for if the plate be allowed to remain ulceration and hæmorrhage are certain sooner or later to supervene, leading invariably to a fatal result.

HOSPITAL REFORM.

OUR hope that the discussion of this subject in the lay press would bring out the principal facts in the case and with them the sympathy and support of our lay contemporaries is being fulfilled more quickly even than we thought. In the *Times* of Saturday is a leading article expressing hearty satisfaction on the elevation to the Peerage of Sir Joseph Lister. The writer goes on to show that the fortunes of the profession have been much injured by the very labours of medical men which, in a degree unparalleled in any other calling, have tended to diminish the amount of demand for their own services. The article then proceeds to deal with the question of hospital reform and practically admits everything which the labours of our Special Commissioner and the efforts of hospital reformers have brought to light. There is a generous admission of the fact that the reformers have no intention of injuring hospitals so far as the relief of deserving cases goes. "Nothing is more curious," says the *Times*, almost paraphrasing our own words, "than the way in which

Hosted by Google

persons who would be ashamed either to ask for charity in any other form or to receive it feel no compunction in entering a hospital where their board and lodging are paid for by the subscribers." The out-patient abuse is stated with equal clearness. "Of the out-patients a considerable number are people earning good wages." The demoralisng effect on the unfit patients is well brought out: "the first visit leads to subsequent ones, until at last the very notion that it is part of their duty to provide themselves with medical attendance seems to drop out of their consciousness." One deep root of the evil is shown to be in the rivalry of the hospitals to show numbers and in the desperate struggle for existence. The special hospitals are proved, by the very nature of their origin, to be special sinners. The article ends by approving of the formation of a central board as advocated by the Lords' Committee and the Charity Organisation Society. The letters published in the papers equally support the contention of reformers. "One who has been driven to the Hospitals" writes in the *Times* that the increase of consultants' fees is a great factor. But there are younger consultants whose fees would be quite practicable to such patients who have no business in hospitals and who take up beds which are meant for the poor.

WHAT CONSTITUTES PLAGUE?

THE highly interesting paper on the spread of plague, by Dr. Cantlie, read recently before the Epidemiological Society of London, which was partly reproduced in our columns last week and which is completed in our present issue, raises, together with the discussion which followed it, some important points. From an epidemiological standpoint the more practically important question is as to what is the precise nature of certain glandular swellings, with or without fever, which there is evidence to show are at times not uncommon, when what is recognised as true plague is prevailing, but as to the nature of which there is much difference of opinion. Dr. Cantlie's mental attitude towards the question is clearly an open one, but he has obviously been much impressed by the recent news from Calcutta of the discovery of a bacillus strongly resembling that of plague in cases to which the name of "pestis ambulans" is given by some, and he referred also to certain peculiar glandular swellings, whether of the groin, armpit, or neck, which were noticed among persons at Hong-Kong and elsewhere, but which were, it appears, never accurately diagnosed. By some observers, however, certain of these glandular swellings have been regarded as being venereal in character, but it is not at all clear from the evidence forthcoming whether the glandular swellings in question may not have been of more than one sort; that, in fact, there is truth in all the observations. Dr. Manson, for instance, pointed out that in the East non-venereal buboes are very common, and he raised the question whether possibly "river fever," which is frequently accompanied by buboes, might not turn out to be a phase of "pestis minor." It is clear that if during certain prevalences of plague there exist glandular swellings which are not regarded as due to the poison of plague, but which, for aught we know to the contrary, may be potent for infection, the preventive measures with regard to the disease will have to be much extended. That there should occur during epidemics of plague a number of more or less anomalous cases is what, upon general epidemiological principles, is, perhaps, to be expected. A similar condition of affairs is frequently observed in epidemics of diphtheria, scarlet fever, typhus fever, and enteric fever. The question is certainly one of great practical importance, as may be inferred from the fact that the exodus from Bombay has now amounted to between 100,000 and 150,000 persons. Dr. Lowson's valuable observations as to the bacteriology of the disease were very full and suggestive, and he threw much doubt upon the discovery of the true plague bacillus in the soil of Hong-Kong as also upon the value of certain methods of treatment. His experiences with regard to the inoculation of pigeons with plague bacillus were somewhat reassuring, as if, as has been stated, these animals can act as the winged messengers of plague it would be necessary to limit their movements as far as practicable. The question of the infection of rodents is one upon which more light is needed, as it seems doubtful whether rats are, as has been believed, infected prior to the human species or whether only the incubation period in rats is shorter than in man. In this connexion Dr. Cantlie's observations as to the similarity in geographical distribution between plague and a certain sub-family of rats seem to call for further investigation. The question raised by Dr. Lowson as to the presence of plague at Singapore is one which may have a very material bearing on the spread of the disease eastward.

AN INTERNATIONAL JOURNAL.

WE notice elsewhere the contents of the first issues of a new literary venture of a peculiarly attractive and interesting nature, for which we hope much practical support will be given by the medical profession in this country. We refer to the revival of the periodical *Janus*, which in the Fifties obtained a notable position from the character of its contributions and the eminence of those who wrote in it. That it did not then obtain a permanent footing is, perhaps, explicable on the ground that its subject-matter—that dealing with the history of medicine—failed to attract a sufficiently large circle of readers. At the present time, when students of medical literature have so vastly increased in number, we may hope that no such drawback will be found to exist. The editor of the new series of *Janus* is Dr. H. F. A. Peypers of Amsterdam, and the basis on which the journal is established is strictly international. Amongst the names of those in this country who have coöperated in its foundation are Sir Joseph Fayrer, Dr. J. F. Payne, Dr. C. Creighton, and Dr. A. Davidson. It must not be supposed that it is intended to limit the scope of the journal to matters of purely archaic interest, for it is expressly stated that medical geography as well as history will be represented in its pages. Thus there should be found in this review articles written in all parts of the world concerning the distribution and character of endemic diseases that may be of great value. As we have indicated, the numbers already issued augur well of the success which should attend an enterprise that ought to stimulate and extend the study of questions in which all medical men cannot fail to feel an interest.

SUFFOCATION IN A WELL.

A FATAL case of asphyxia has occurred at the waterworks of the Hastings Corporation at Brede. The well, which had been sunk for two years, was sixty feet deep and was lined with iron cylinders for twenty feet, with brick-work for the remaining forty feet. There were fourteen feet of water, and the well was left open, but was under a shed. At a depth of seventeen feet one of the workmen named Williams, was suddenly overcome and fell into the water. Another man followed to help him and got down about forty feet when he was overcome and was hauled up by the feet unconscious. Suspecting foul air, the men sent to Hastings for a fan and then got the body out. Men who had been in the well "hundreds of times" said they had never before known foul air to be in it. It was usual to let a lighted candle down to test the air, but on this occasion this small formality had apparently been omitted until after the catastrophe, when it was repeatedly extinguished at a depth of twenty feet. The man Britt, who went to the rescue, said he smelt "damp air" about thirty or forty feet down,

Hosted by Google

and feeling "very funny" was about to call to be pulled up when he suddenly lost consciousness. The medical evidence pointed to death by drowning with evidences of carbonic acid poisoning, and the jury, being satisfied with the precautions that were taken and of opinion that the gas had suddenly been generated, returned the usual verdict. To this verdict should have been added, we consider, the rider that the simple precaution of testing the air of deep wells and similar places by means of a lighted candle should never be omitted, and it is the duty of those authorities connected with such undertakings to insist upon this test being applied before a descent is made. We are not inclined to accept the theory of sudden generation. At any rate such an occurrence is rare. The gradual accumulation of carbonic acid gas in wells situated in chalky districts is, on the other hand, a not uncommon event. We think in the present instance some further inquiry should have been made as to why on this particular occasion the simple but, as it often proves, life-saving test was neglected.

HENOCH'S PURPURA.

IN a recent number of *Pediatrics* an interesting paper by Dr. G. A. Sutherland appears, dealing with this curious and somewhat unusual disease and giving particulars of three cases of what he considers to be the same condition which have come under his own observation. The first was that of a male child aged three years and nine months, who had had, three months before his admission to hospital, a rash which had been supposed to be measles. Ever since he had been dull and languid with occasional pain in the stomach, and a month after the first rash appeared he began to suffer from sickness after food and a rash came out on his arms and legs, which had disappeared and appeared several times afterwards. A few days before admission he had become drowsy and had complained of abdominal pain. He had also vomited some chocolate-coloured material and passed bright red blood per rectum. There was nothing important or significant in his previous health or in the nature of his food, and on admission he was well nourished and of good colour. There was an eruption on his arms, feet, and legs, and a few spots on his back, buttocks, and abdomen. The gums were healthy, and physical examination revealed nothing abnormal except pain on pressure over the abdomen. During his four and a half months' stay in hospital hæmorrhages on the skin appeared abruptly on several occasions—twenty-five in all. The spots did not disappear on pressure; they were small and sharply defined, sometimes not elevated, but sometimes papular. They were not irritable, and although the eruption was wide-spread and general the parts chiefly affected were the extensor surfaces of the arms, the buttocks, the front of the legs, and the dorsa of the feet. There were, also, on eleven different occasions attacks of severe abdominal pain accompanied or followed by vomiting of blood-stained matter or the passage of blood from the bowel. The urine contained albumin and sometimes blood, and hyaline and blood-casts were present in great number. One curious point is that the knee-jerks were not obtained during the first seven weeks of his stay in hospital. He was seen two months after his discharge and had remained free from abdominal pain or hæmorrhagic outbreaks. The second case was that of a girl aged seven years, and the clinical history was characterised by attacks of abdominal pain, with vomiting of blood, melæna, bleeding from the nose and gums, together with repeated outbreaks of purpuric eruption, chiefly on the arms and legs, and albuminuria and hæmaturia. In this case also the knee-jerks were not obtained. She was in hospital for three months and was discharged recovered. She relapsed, however, two months later, and developed symptoms of intussusception with suppurative peritonitis, of which she ultimately died. Dr. Sutherland offers as an explanation of the final accident in this case that advanced by Werlhoff in reference to a similar case—viz, that there had been a hæmorrhage into the wall of the intestine causing paralysis of that part and increased muscular contraction in the adjoining part, leading to invagination of this into the paralysed and hæmorrhagic part. The condition found post mortem agreed with such a view, but nothing was found to throw any light upon the occurrence of the hæmorrhagic eruption of the skin. A third case, similar in many ways, is also detailed. The patient was a girl aged ten years, who had attacks of abdominal pain, sickness, epistaxis, and melæna, with purpuric skin eruption and the presence of blood and albumin in the urine. She also had articular pain and swelling, but she recovered. Dr. Sutherland, in conclusion, sums up the chief characteristics of this disease and points out the differences between it and other forms of purpura. The paper altogether is interesting, and it is embellished with two beautiful illustrations from photographs which show the character and distribution of the eruption in a very satisfactory manner.

THE FLANNEL SHIRT CLUB.

HOSPITAL patients who are sufficiently recovered to be discharged are only too often sensible of a painful contrast between the warm clothing to which they have become accustomed and the scanty habiliments resumed at the time of their return home. A Flannel Shirt Club has, therefore, been formed by an association of ladies, of whom the Countess of Strafford is president, its object being to supply good flannel shirts to needy male patients when they are discharged from London hospitals and infirmaries. Mrs. H. H. Clutton, the honorary treasurer, will receive and acknowledge subscriptions and donations of money sent to her at No. 2, Portland-place, W. All shirts and materials should be sent to the honorary secretary, Miss Lamport, No. 52, St. John's-wood-road, N.W., from whom information and forms of membership may also be obtained. The particular form of charity which this association will dispense is obviously both judicious and philanthropic.

INFANTILE PARALYSIS.

IN the last number of the *Neurologisches Centralblatt* an abstract of a very interesting paper by Professor Medin is given, the original having appeared in a Swedish paper. In an epidemic in Stockholm in 1887 the writer had collected 43 cases, and between 1888 and 1894 29 sporadic cases, and again in an epidemic in 1895 21 cases. The immediate cause of the disease he believes to be a poison, but infection from one patient to another, although possible, is very rare. No particular conditions can be regarded as predisposing, although children under four years of age seem to be most affected, and both epidemics occurred in late summer. Most cases began with fever and sickness, pain and sensitiveness of the body, rarely convulsions, but occasionally sighing and crying out. Of 50 cases, the legs were affected in 45, the arms in 14, and in 4 cases the face or the external rectus or muscles supplied by the third nerve were affected. Six cases of acute polyneuritis were observed in the 1887 epidemic, but only two in that of 1895. In that disease the onset was sudden, with high temperature, and the pain was severe; sometimes there was cutaneous hyperæsthesia, and in one case this followed anæsthesia in the lower limbs. Poliomyelitis affecting the nuclei in the bulb and pons was found in several cases and a lesion in the cells in

Hosted by Google

this region was in several cases demonstrated, practically identical with that of the anterior horn cells. Professor Medin has also seen polio-encephalitis occur in the same epidemic, indicating an apparent identity of the poisons of the two diseases. The prognosis is worst if the lumbar cord is affected, less if the cervical is the part affected, and is more favourable in polyneuritis than in polio-myelitis. The conditions found post mortem were the signs of general infection proceeding from bloodvessels and causing acute inflammation in the anterior horn, with consequent degeneration of the ganglion cells and of the nerve fibres. Professor Medin regards the disease as an independent and peculiar one and separates from infantile paralysis all paralytic conditions which occur in association with other infective processes.

GLOUCESTER AND THE NATIONAL MEMORIAL TO JENNER.

WHILE the exact form of national memorial to Jenner is yet undetermined it is proper to remember that the Jenner Society of Gloucester has been in the field as a local society for purposes similar to those of the committee in London now organising a national movement. Gloucestershire has a peculiar place in this question. It was in Gloucestershire that Jenner's immortal discovery was made and confirmed. Alas, it was in Gloucester itself that the light of Jenner's discovery went out almost completely, with the result that hundreds died during last year for want of vaccination, but with the effect of scaring the survivors into a rush to the vaccination stations. A society of enlightened citizens of Gloucester, calling themselves the Jenner Society for promoting the honour of Jenner and a knowledge of the real truth about vaccination, was formed at an early stage of the epidemic which has so terribly afflicted Gloucester. Dr. Bond, the honorary secretary of this society, has forwarded to us a printed statement of the objects of the society and especially of its plans for circulating sound and instructive literature on the subject. We sincerely hope that the London Committee for the national memorial will consider the claims of this society to affiliation and will apportion a grant from its funds for the literary defence of vaccination as provided for in the publications issued by the Jenner Society.

THE PLAGUE AT BOMBAY.

AS regards the epidemic of bubonic plague at Bombay it is always difficult to ascertain the figures representing the exact prevalence of the disease at any given time, but there does not seem to be any doubt that the state of affairs in Bombay is very serious. The Government returns are reliable as far as they go, but they do not usually afford the latest information, for which we have frequently to depend upon telegraphic intelligence from other sources. There has been an enormous exodus of the population from Bombay, and it is still going on; business is temporarily paralysed and more or less panic prevails among the native population. The total number of cases of plague returned to the end of December last amounted to 2430, with 1735 deaths; and during the first two days of the present year 130 fresh cases occurred, of which 120 are stated to have proved fatal. The general death-rate of Bombay is also excessive; nearly 1000 of the deaths that occurred during the last week of 1896 were attributable to the various kinds of fevers and 90 to bubonic plague. Altogether, 11 Europeans are stated to have been attacked since the outbreak, 2 of whom had died, and there were, according to the Central News Agency, 3 Europeans in hospital on Dec. 31st suffering from the disease. Cases of plague have, as we said last week, likewise been reported as having occurred at Karachi and Poona. At the former place the disease is stated to be assuming a very virulent form. Surgeon-Major Robert Manser, who held the post of senior physician to the principal native hospital in Bombay, is, we regret to say, reported to have died from plague on the morning of the 6th inst. The health of Calcutta, according to the latest intelligence that has reached us, seems to be fairly satisfactory, but the news from Bombay is rather alarming. It is stated that at Karachi the plague is taking an extremely virulent form, and that the panic in Bombay is increasing. Surgeon-Major-General Cleghorn, Director-General of the Medical Service, has left Calcutta for Bombay to report upon the plague. We print in another column (p. 131) a very interesting account sent us by an eye-witness in Bombay.

PUBLIC HEALTH AT MONTREUX AND TERRITET.

THOSE of our readers who may have friends residing at Montreux and Territet will welcome the announcement that the rumours as to the existence of typhoid fever in that well-known health resort are quite unfounded. Our information is derived from a most trustworthy source and refers not only to the town itself but to the surrounding district. Last year there was an epidemic of very mild scarlet fever, in the course of which there was only one death, and not a single case has occurred since last spring. The water-supply is of the purest description, being derived from Les Avants. The water reaches Montreux under a pressure of about six atmospheres, and there are no cisterns in the town the service being constant.

STREET NOISES.

THE agitation against totally unnecessary noises is slowly growing and we begin to see some likelihood of, if not relief, at any rate legislation towards that desirable end. The Parliamentary and General Purposes Committee of the Islington Vestry have approved of the adoption in London of a by-law suggested by the Home Secretary. This by-law, which is most admirable, is in force in various provincial towns and runs as follows:—

"No person shall, for the purpose of hawking, selling, or distributing any newspaper or other article, shout or use any bell, gong, or noisy instrument in such a manner as to cause nuisance or annoyance to the residents or passengers."

The County Council are we believe considering the subject as well, so we have hopes that even if we cannot

"Forget six counties overhung with smoke
* * * * * *
Forget the spreading of the hideous town"

the said town may be made less hideous by the silencing of the demon "winner" shouter, the even more offensive fog-horn voiced ruffians who howl in pairs, and the snuffly infant who comes out on Sundays.

HÆMORRHAGIC PANCREATITIS IN AN INFANT.

MCPHEDRAN[1] records what he claims to be the only case in an infant of this rare disease. Of all previous cases the youngest was twenty years of age and the majority about forty-five years. The patient was a male infant, in good health, with a tendency to constipation. In the ninth month the mother became pregnant, and he failed slightly in general condition. Weaning was attempted and peptonised milk given. He vomited and refused everything but the breast. Therefore the attempt was abandoned. On resuming suckling he vomited profusely, became prostrate, and was attacked with colic. On the next day he was in great distress and pallid. All attempts to give nourishment were followed by vomiting. He was constipated, and calomel followed by repeated doses of fluid magnesia failed to produce effect. Only a smal green motion, chiefly mucus, was passed. The abdomen was slightly distended. In the region of the ascending colon was an elongated mass about the size of the middle finger,

[1] Canadian Practitioner, September, 1896.

Hosted by Google

extending from the costal margin to the iliac crest. It was firm, dull, and moved with respiration. Intussusception was suspected and laparotomy performed. The mass was found to be an accessory lobe of the liver. The intestines and peritoneum were healthy. Death occurred next morning. Only partial necropsy was allowed, which took place forty hours after death. The middle third of the pancreas and its immediate surroundings were found deeply infiltrated with blood. Microscopic examination disclosed nothing more, as the organ was so much decomposed. Bacteriological examination showed the presence of only one form, a bacillus resembling those of the proteus group. The bacillus coli communis was carefully sought for.

MEDICAL STRIKE IN PARIS.

THERE is a "doctors' strike" in Paris which opens out the whole question of fees for attending the poor and indigent. The Prefecture of Police had established what was called a night medical service, and certain practitioners appointed for this purpose were to hold themselves ready to go out at night whenever called upon for some emergency. As this service was to be rendered only to poor people the medical officers were to receive a fee of 10 francs from the municipality. The authorities, however, did not calculate on the great number of poor who dwell in Paris and on the frequency with which these emergencies arise. Thus it has been found that these 10 franc fees amount in all to a very large sum, and the Prefect proposes to replace them by a regular income. This has been fixed at 600 francs, or £24, per annum, a sum which is quite sufficient for the medical men who live in wealthy districts, where there are not many poor people who would require their services. In the eleventh arrondissement, however, this would reduce the medical fee from 10 francs to an average of 3 francs and the four medical officers of this district have given in their resignations rather than submit to be constantly called out at night for a fee which is little less than half-a-crown. The Prefect laughs at this strike, for he thinks that for one medical man who resigns there are scores of others who will only be too glad to take up the position. It remains to be seen, however, what the Paris Medical Syndicate, with its 600 members and its seventy provincial branches, will have to say on the matter. Perhaps, in spite of this syndicate, the medical men will be defeated; but, whether they win or lose, the incident will in any case teach them the value of organisation.

THE CAUSES OF APPENDICITIS.

SOME points of interest in connexion with the pathogeny of appendicitis were discussed at a recent meeting of the French Société de Chirurgie. The view of M. Dieulafoy, that the disease is a consequence of constriction with closure of the appendix and the consequent retention of morbid material within it, did not find much favour. On the contrary, several speakers referred to the frequent existence of this condition without appendicitis, and at the same time mentioned cases in which they had found a perfectly permeable appendix to be the seat of inflammation. The general opinion of those who took part in the discussion was that appendicitis is usually only the local expression of a more or less general enterocolitis. The theory of M. Reclus is worth quoting as a more detailed statement of these opinions. According to him the problem of causation is capable of a double solution—(1) as being related to the presence of an actual foreign body in the appendix, a condition of course hostile to spontaneous recovery, and (2) as explained by a "theory of stagnation." This view regards the appendix and in a less degree the cæcum as diverticula which readily allow the accumulation within them of organic fluids, these in turn becoming the seat of fermentative changes. Inflammation follows as a natural consequence. In this comprehensive and moderate statement we shall probably find the nearest approach to explanation of a malady the clinical aspect of which is, as a rule, sufficiently obscure.

"THE LANCET" RELIEF FUND.

THE "Application Form" of THE LANCET Relief Fund will be found in our present issue, and can be readily detached should occasion arise for its use. We again take the opportunity of asking those of our readers who may have occasion to employ the form or to sign one of the required accompanying certificates to carefully note the conditions on which applicants become entitled to a participation in the benefits of the Fund. All applications should be made to the Secretary, Mr. Edward Davies, THE LANCET Offices, 423, Strand, London.

A NEW THEORY OF CANCER.

A CORRESPONDENT sends us a pamphlet printed at Glasgow entitled, "A New Theory of Cancer, with its probable Cause and Cure; or, the Answer to a Twelve Years' Prayer." This effusion, which is, we believe, written by Mr. Coyle, L.F.P.S. Glasg., is a compound of some medical knowledge intermixed with passages of the sort of stuff we find in "Dreams" or "The Book of Mormon." As Mr. Coyle is, we fancy, the defendant in an action in which the statements contained in the pamphlet in question are to be brought forward we must at present refrain from any further comment.

DEATH FOLLOWING VACCINATION.

THE *post hoc ergo propter hoc* fallacy has never been more abundantly exemplified than in alleged deaths from vaccination. Again and again inquiry has shown that the real cause of the death of an infant has not the remotest connexion with a vaccination which has been performed at a date more or less approximate to the fatal illness. On the other hand, it is well to recognise that injuries are caused by vaccination, and that this operation, trivial as it may appear, should never be undertaken in a weakly subject or without every safeguard. A case was recently investigated by a coroner's jury at Southampton where a child five months of age died on Dec. 21st after a brief illness from what the medical evidence showed was septic poisoning. The infant had been vaccinated on Dec. 9th, having six weeks previously suffered from bronchitis. There was no inflammation of the arm, but the site of vaccination became discoloured, and the medical witness who made the post-mortem examination considered that this was the cause of the septicæmia. We are bound to say that there is very little evidence to support this theory, especially as there was proof of exposure to inhalation of sewer air.

RAPIDLY GROWING OVARIAN CYST.

A POINT of great interest in the case of ovarian cyst detailed by Mr. Butler-Smythe in another column is the evidence which it affords as to the rapid growth of an ovarian cyst. At the earlier operation the right ovary was taken into the hand and carefully examined and nothing was then seen to be wrong with it; and fourteen months later, when the patient was confined, the ovary was still apparently normal, for though a small cyst might easily have escaped notice unless the abdomen had been specially examined, yet a large cyst could not possibly have been overlooked. About ten weeks after this the tumour had attained a size sufficient to hold thirty pints of fluid. We are so little acquainted with the laws governing the secretion of liquid in cystic tumours that we are utterly unable to say why in one case a cyst may be several years in reaching this size, and in another, such as the

Hosted by Google

one reported in another column, the whole process has not lasted more than a few weeks. Undoubtedly the rapid diminution of abdominal pressure occurring after labour may be credited with some influence. Another point worthy of note is the tendency seen in this case and observed in so many others for both ovaries to become cystic successively. The removal of a cystic tumour of one ovary appears to have some influence in determining the cystic degeneration in the other. Probably the effect is only apparent, the correct explanation being that both ovaries have the tendency to become cystic, but do not manifest this tendency synchronously.

DANGEROUS SOMNAMBULISM.

A SENSATIONAL case of somnambulism is reported from Brussels, which happily ended without any disastrous results. The individual concerned was a pupil in one of the religious educational establishments of that city. In the middle of the night he was found walking about clad only in his sleeping garments, and on being followed he was seen to have a large kitchen knife in his mouth, and was occupying himself in passing his hand over the throat of one of the sleeping pupils. He was at once awakened and so possibly prevented from doing some terrible damage. It is said that the lad is a son of a butcher, and he states he dreamed he entered into his father's business and that he went into the kitchen for a knife, with which he wanted to kill the pigs. Midnight somnambulists of this class are very dangerous and there seems every probability that some of the sleepers would have lost their lives had not the would-be butcher been found in time, for in these cases the special senses usually perceive things only in relation to their dream, and so, while being able to see the things connected with his object in view, he would be oblivious to the other surroundings and fail to realise his position. The disorders of sleep are probably in most cases due to differences of functional activity between different parts of the cerebrum; thus, while some are inactive others remain active and, indeed, in some cases become overactive. Talking during sleep is one of the simpler examples of activity of some parts of the nervous system while others are out of action; but walking and doing definite actions is far more complicated and may be dangerous both to the individual concerned and others who may chance to come in his way.

ANTI-STREPTOCOCCIC SERUM.

THE results obtained hitherto in the treatment of septicæmia by means of the antitoxic serum of Marmorek have been very much less marked than those which have followed the antitoxin of diphtheria. Its use in the treatment of puerperal fever has not been attended with brilliant success. It is to be remembered, however, in this connexion that the serum has in some, and probably in many, instances been injected after the disease had become well-established in the system of the patient. In view of the very rapid absorption of the septic poison in these cases, and of the large uterine surface available for this purpose, the significance of such delay should not be overlooked. It is probable, too, that the disease under treatment has not always been the effect of the streptococcus alone, but primarily sapræmic and a consequence of putrefaction in retained coagula. It is, however, encouraging to note that even in the treatment of puerperal cases a distinct amelioration of symptoms after injection has been noticed by some French observers (Patru, Maillart, Ribemont, &c.). M. Boucheron[1] speaks highly of his results in the treatment of purulent dacryocystitis by this method, injections of 5 c.c. repeated at intervals of a few days having a marked effect even in chronic cases of this disease. He employs the serum also as a preventive of possible suppuration after cataract operations. As yet it would seem that the antitoxic power of this remedy is not great, and it may be that the secret of success in acute cases lies, not only in the promptitude of its employment, but in the frequency of its repetition. The most that can be said so far is that past experience, though indecisive, is encouraging rather than otherwise, and lends some colour to the hope that with a purer and more powerful serum better results may be expected. Practitioners who have had to combat the horrors of puerperal septicæmia are not likely to undervalue even such hope in this connexion.

[1] Presse Medicale, Nov. 18th, 1896.

HOUSE SURGEONS' FEES.

ON Jan. 3rd an inquest was held at the Croydon Hospital on the body of a patient who had died in the institution. It appears that the coroner "consented" to a post-mortem examination being made, as he said, "in the interests of science," but whether he issued an order for the same is not stated. That, however, matters little. It is strange that it is not universally known by this time that a medical man who has attended a patient at a hospital, workhouse infirmary, or other public institution—the death having occurred in such place—cannot recover fees for making a post-mortem examination or for giving evidence at an inquest. At the inquiry referred to we learn that the locum tenent for the house surgeon complained that he was not allowed remuneration, and according to the newspaper reports there was a sharp passage of arms between the medical gentleman and the coroner, which culminated in the latter threatening to commit for contempt of court, The incident is to be regretted, but whatever the ethical merits may have been it is clear that the coroner was legally right. It is sometimes difficult to obtain an order from a coroner for a post-mortem examination. To make one without his order or consent is to be guilty of an assault on the body—a punishable offence. In this case the coroner allowed a necropsy "in the interests of science," and for this the profession should be grateful. Anything which tends to clear up the mystery of the cause of death is desirable. We cannot see on what grounds a medical man can take offence when he is not paid for work which the Act of Parliament distinctly says shall be done without fee.

THE FAMINE IN INDIA.

AMID the conflicting statements that have been made from time to time regarding the extent and severity of the famine to be anticipated or actually existing at the present time, it is a very puzzling problem for the perplexed newspaper reader to form a correct estimate of the real condition of affairs in India in respect of any present or prospective famine in that country. It is generally admitted, however, that there is a very large and unusual amount of distress among the natives of India at the present time owing to the scarcity and high prices of food, and that this distress threatened at one time to be enormously increased and aggravated in its area and intensity by a failure of the cold weather rains. Rain has, however, fallen to some extent over most of the affected districts, and the Government of India should soon be in a position to form some idea of the estimated dimensions of the scarcity and the proportions of the disaster that will have to be dealt with. Wherever rain has fallen at all copiously the prices of food have also fallen, but the amount of rainfall has, in many parts of the country, been quite inadequate, and we are still unable to form a correct estimate of the situation. We gather from the *Times* that the Government of India have, however, now secured full reports from all local administrations regarding the famine and the

Hosted by Google

state of the crops, and that an early opportunity will be taken to make a public statement in the Legislative Council on the subject. Meanwhile, close attention is being paid to the question of food supplies in areas where famine already prevails. We should consequently soon be in a position to form some notion of the extent of charitable aid that will be required from this country for the distressed natives of India and the organisation that is proposed for dispensing it in the most effective way. From the latest accounts we infer that the famine is likely to be severe and widespread, and that the sooner the Famine Fund is started in this country the better. A very large proportion of the populations of India are at the best of times miserably poor and the daily struggle for a bare subsistence is hard enough. Famine or any increased scarcity of food is immediately followed by an increased amount of sickness and mortality.

THE HEALTH OF LORD ROSEBERY.

WE are glad to be able to give a favourable account of Lord Rosebery's condition. On Thursday he was practically convalescent; the temperature was normal, there were no complications, and he was allowed to get up. As from this it will be seen that the attack has been but a slight one it is reasonable to hope that Lord Rosebery will escape the wearisome insomnia which resulted in 1895.

MEDICINE will rejoice with the other sciences to learn that Mr. Herbert Spencer has consented to sit for his portrait in response to a circular letter signed by some eighty well-known leaders of thought. The effect which the System of Synthetic Philosophy has had upon modern intellectual development can be exaggerated with difficulty, and to the student of more than one side of medicine this fact is very well known. An account entitled "The Herbert Spencer Portrait Fund" has been opened at the Western Branch of the Bank of England, Burlington-gardens, W.

THE fifth award of the Reuben Harvey Memorial Prize will be made on July 1st, 1897. The competition is open to all students, licentiates, and graduates of the various schools of medicine in Dublin which are recognised by the medical licensing bodies in Ireland, and is of the value of £25. Further details will be found in our advertisement columns.

THE annual general meeting of the Neurological Society of London will be held at the rooms of the Medical Society, 11, Chandos-street, Cavendish-square, W., on Thursday, Jan. 14th, at 8.45 P.M., when Dr. G. H. Savage, the President-elect, will deliver his inaugural address on Heredity in the Neuroses.

DR. G. SIMS WOODHEAD, F.R.S. Edin., Director of the Research Laboratory of the Conjoint Board of the Royal Colleges of Physicians and Surgeons, has been elected President of the British Medical Temperance Association in place of the late Sir B. W. Richardson.

THE Council of the British Institute of Public Health have awarded the Harben medal for 1897 to Professor M. von Pettenkofer, Emeritus Professor of Hygiene in the University of Munich, in recognition of his distinguished services to the public health.

BACTERIOLOGY IN 1896.

IN the year 1896, though much valuable and permanent work was done in the department of bacteriology, there has been no event comparable in importance to the anthrax, tubercle, cholera, or diphtheria discoveries of some recent years. It has not, however, been a year of "marking time," and some of the published investigations are of such solid character that they must be looked upon as really important contributions to bacteriological science. What strikes the observer most is that an attempt has been made, not to start fresh and striking theories, but to gain an appreciation of those that have been advanced and to see how far well-recognised facts fit in with them.

The application of observed bacteriological facts and rules to therapeutics has had a much wider and more far-reaching influence than could at one time have been anticipated, whilst the relation of bacteriology to the etiology and diagnosis of disease has during the last year become closer and more and more important since various modifications of Pfeiffer's reaction have been brought into use. Almost all the new work that has been done bears on the action and inter-action between micro-organisms and living animal tissues, either as seen in the animal body itself or as resulting in the storage of certain active products in the blood, and separable from the serum of animals affected with certain specific diseases or treated with the products of the bacteria associated with these diseases.

Early in the year Dr. Louis Cobbett confirmed the observation that even the blood serum of normal horses may possess definite antitoxic power against diphtheria poison. He also supported the suggestion that there are two different therapeutic agents present in the serum of immunised animals, one acting against the toxin and the other against the bacilli by which the toxins are formed, and that the formation of this antitoxic serum is in great measure independent of, though often necessarily running parallel with, immunity of the tissues, either locally or generally. A few months later Dr. Cartwright Wood read a communication (a full abstract of which appeared in our columns) to the Royal Society, in which he reported a most important improvement in the method of producing antitoxins rapidly and in large quantities. By using the diphtheria "albumoses" described by Dr. Sidney Martin and injecting them in large quantities at short intervals he was able to obtain diphtheria antitoxin of considerable potency (125 units per c.c.) in twenty-eight days, a result never hitherto obtained, whilst by combining injections of ordinary broth toxin with his "albumose" injections he, as recently reported in our columns, obtained diphtheria antitoxin of greater potency than has, so far as we are aware, yet been obtained in large quantity. The importance of this investigation is apparent when the advantages of this method, as brought forward by Dr. Wood, are considered: (1) that powerful diphtheria antitoxins can be produced without risk in a much shorter period than has been previously possible; (2) that much more powerful antitoxins can be easily produced, so that the amount necessary to be injected into a patient can be greatly reduced, and one of the great objections to its introduction into private practice in this country can be removed; and (3) that the greater strength of the serum will permit of the patient receiving at the beginning of treatment a sufficient quantity of the serum at one injection, when, as is universally recognised both by animal experiment and clinical experience, its curative action is exerted most markedly.

From the reports that we were constantly receiving from members of our profession it soon became evident that owing to the difference in standards of measurement and nomenclature much confusion existed as to the relative strengths and desirable doses of the various anti-diphtheritic serums on the market. We therefore appointed Special Commissioners to inquire into the whole question of strength of these serums in order that the relative doses might be fixed. These results were in many cases remarkable; but as the relative strength of each was obtained a medical man, taking Behring's serum as a standard, could calculate what dose of any other serum must be injected in order to introduce a dose of a certain number of units. We have reason

Hosted by Google

to believe that the information thus afforded has been of considerable assistance to those who have to work with anti-diphtheritic serum and has contributed in some measure to the improvement of the serum treatment in this country and to putting the dosage on a rational and intelligible basis. Before leaving the serum question it must be pointed out that anti-streptococcic serum and anti-tetanic serum have both been successfully prepared at the laboratories of the British Institute of Preventive Medicine, but as yet the cases treated with them are not sufficiently numerous to afford any very satisfactory statistics. Quite recently Dr. Washbourn has announced that he has been able to produce a serum which exerts a distinct protective action against the streptococcus of pneumonia. In connexion with this work, too, he has been able to produce what must be looked upon as a saprophytic or non-malignant form of the pneumococcus and from old cultures an extremely resistant and persistent form of the same.

One of the great questions of the year has been the value of the various modifications of Pfeiffer's reaction in regard to the diagnosis of various diseases. The reaction first indicated by Bordet and worked out by Durham has, in the hands of Widal, Grünbaum, Wyatt-Johnston, Delépine, and others, given most accurate results in the case of typhoid fever, and there is every prospect that this method will, before long, come into very general use and give as accurate results as have been obtained in diphtheria by microscopical and cultural examinations. Durham observed that the action of dilute serums of highly immunised animals on susceptible microbes was to cause them to become aggregated into clumps even *in vitro* and observable with the naked eye, the clumps falling to the bottom of the tube and leaving a clear supernatant fluid. Using this method for diagnostic purposes in the case of typhoid fever the reaction can be observed under the microscope and also *in vitro*. All the observers who have done work on this point have come to the conclusion that the antitoxic property of typhoid serum is developed at a comparatively early stage of the disease, and that once developed it enables the diagnosis to be made with a comparative degree of certainty.

The outbreaks of typhoid fever that have been supposed to be associated with infection through the ingestion of oysters from beds or "layings" contaminated with typhoid-laden sewage have led to the appearance of two important reports on this question of infection through oysters. Dr. Cartwright Wood in his report brings forward most important evidence as to the possibility of infection by oysters contaminated with typhoid sewage. He shows that cholera organisms may be demonstrated experimentally as continuing within the oyster for eighteen days, whilst in infected water in which oysters were placed they could be found for as long a period as two months, whilst typhoid organisms under similar conditions remained for three months. Dr. Klein says that these organisms may persist in sea-water tanks for two or more weeks, the typhoid bacillus retaining its characteristics unimpaired. In one case Dr. Klein found Eberth's typhoid bacillus actually within the oyster. All this evidence goes to prove that disease germs are much more persistent in sea-water than has been generally imagined, and although it may be, as Dr. Thorne Thorne insists, that it is only under special conditions that we find typhoid fever and cholera ensuing as the result of consuming oysters laid in polluted waters, such cases as are traced to this source necessarily form a very small percentage of the cases actually so infected, whilst these, again, bear a very small proportion to the cases that are infected by them. The whole bearing of these reports on the question of infection is extremely important, and the bacteriological investigations published during this year will have a wider bearing on the subject of the contamination of water, whether fresh or salt, than has any work that has been done for a considerable period.

The outbreak of bubonic plague in India affords a most striking object lesson or demonstration of the modification of a pathogenic organism, as evidenced by the virulence of the disease set up by it at different periods of an epidemic. When first it was announced that the plague had broken out in Bombay the percentage of deaths was exceedingly low, and for some time a large proportion of the cases attacked were comparatively mild. Recent reports, however, indicate that not only has the number of cases increased at an alarming rate, but the percentage death-rate has gone up in a corresponding fashion, whilst we have further evidence of the increased virulence of the organism in the fact that Europeans, who in the first instance were not affected, are now attacked in considerable numbers. Metschnikoff's experiments on cholera and on the exaltation of the virulence of the organism, the difference between infection by the blood and infection by the alimentary canal, and his observations on the toxins produced by cholera organisms are of very great interest; whilst the observations made by numerous other observers on the production of cholera and typhoid toxins and antitoxins continue to add to the sum of our knowledge on these subjects.

The filtration of water, especially in relation to the elimination of bacteria, during the year occupied considerable attention; whilst, as was pointed out in the Report of our Special Commissioner on the Utilisation of Micro-organisms in the Purification of Sewage,[1] certain advances have been made as regards the conversion of sewage materials into inert substances by the action of bacteria. This question, started on a practical scale by Mr. Scott Moncrieff, had been suggested as a possible method by chemists some fifteen years ago. Mr. Dibdin of the London County Council has proved that the chemically treated sewage may be further enormously improved by passing it through coke breeze filters in which numerous organisms have been allowed to grow; whilst Mr. Cameron, borough surveyor of Exeter, has carried out a long series of experiments in which he has been able to confirm the results obtained by other workers, starting, as Mr. Scott Moncrieff does, with the crude sewage. In all these cases the purification, as indicated by the amount of oxygen absorbed, amounts to something like 75 per cent., and the whole of this is put down to the action of bacteria.

During the year the Royal College of Physicians of Edinburgh opened its magnificent new laboratories for the carrying on of pathological, bacteriological, and general experimental research. A well-equipped pathological and bacteriological institute was, under the direction of Professor Joseph Coats, added to the Western Infirmary, Glasgow, in connexion with the teaching of these subjects in the Glasgow University. Among the more important books issued during the year may be mentioned Pearman and Moor's "Applied Bacteriology"; the fourth edition of Crookshank's "Text-book of Bacteriology"; Clifford Allbutt's "System of Medicine," by various authors, in volume 1 of which is an admirable account of infectious diseases, immunity, &c.; and finally Sternberg's "Text-book of Bacteriology," which contains, revised and brought up to date, that portion of his "Manual of Bacteriology," published in 1892, relating to pathogenic bacteria, omitting the detailed descriptions of non-pathogenic forms and the extensive bibliography included in the larger work. The bacteriological work of the year together forms a solid and permanent contribution to scientific and applied medicine and surgery and it certainly offers a most powerful argument to those who wish to see the subject of bacteriology made part of the curriculum of every medical student.

CHRISTMAS AT THE HOSPITALS.

SPECIAL efforts are made at Christmastide on the part of the medical and nursing staffs to brighten the lives of the inmates of our various hospitals. The wards are gaily decorated with evergreens and flowers, gifts are presented, entertainments are provided, and as far as practicable the dietary scale is added to and made to resemble somewhat the festive fare enjoyed by those in health at this period of the year.

King's College Hospital.—In the early morning of Christmas Day a suitable gift was placed by the bedside of every patient in the hospital. These gifts were provided by many kind friends and consisted to a considerable extent of articles of warm clothing and many toys for the children. For dinner there were turkeys, plum pudding, &c., for all the patients who were well enough to enjoy such fare. During the afternoon the patients received their friends. After tea there was a special musical service with carol singing in the chapel, which was decorated with excellent taste. On Boxing Day in the wards, which were also decorated admirably and illuminated with hundreds of candles and fairy lights, there was festival tea for all the patients at half-past four o'clock and an entertainment

[1] THE LANCET, Dec. 5th, 1896, p. 1631.

Hosted by Google

in each ward. The entertainments were given by the resident medical officer, students, and nursing staff, assisted by friends. All passed off most successfully, and both on Christmas Day and Boxing Day the spirit throughout the whole institution was that of happiness, good temper, and enjoyment. The resident medical officers and nursing staff were untiring in their efforts to give pleasure to others.

St. George's Hospital.—On Christmas Day, the wards being very prettily decorated by the nursing staff, the patients who were able to partake of such "good cheer" were provided with roast beef and plum pudding. On the evening of Dec. 28th a "Christmas Tea" took place for all the patients in their several wards, presided over by the lady visitors and their friends, and on Jan. 2nd an entertainment for the patients was given in the Board-room, consisting of "animated photographs," music, &c. Entertainments for the nursing staff have been arranged for Jan. 7th and 8th (to-day, Friday), comprising a dramatic performance given by one of the visiting surgeons and his friends; and on Jan. 14th and 15th entertainments will be provided by the resident medical staff.

Victoria Hospital for Children, Chelsea.—The usual Christmas tree was given to the children on Christmas Day. The annual treat will be given in the second week in January. The wards were prettily decorated for Christmas Day, and the usual dinner of game, turkeys, and plum pudding was partaken of by the patients.

Hospital for Sick Children, Great Ormond-street.—No efforts were spared at this institution to make Christmastide as bright and happy a time as circumstances would allow. The wards were charmingly decorated, and, needless to state, the little ones were not forgotten by Santa Claus. On Dec. 26th a Christmas entertainment was given for the patients and on Monday the out-patients were entertained.

City of London Hospital for Diseases of the Chest, Victoria Park.—On Christmas Day the usual Christmas dinner was provided for the patients, at which some members of the committee of management and other visitors were present. Christmas cards, books, periodicals, &c., were distributed, together with dolls and toys for the young patients. In the evening a musical entertainment was given, which afforded much amusement and pleasure to the inmates of the hospital.

German Hospital, Dalston.—Christmas trees were placed in all the wards, and there was a distribution of useful presents to patients and inmates on Christmas Eve. The carol singing was much appreciated.

Chelsea Hospital for Women.—On Christmas Day, from a fund collected by the ladies' committee, each nurse and member of the household staff received a present, and the Christmas dinner and tea for both patients and staff were provided from the same fund. Each patient was allowed one visitor to tea, during which time the nurses sang carols. On Boxing Day the nurses and their friends gave the patients a concert, consisting of part-songs, solos, and Haydn's *Toy Symphony*, which had been carefully rehearsed. On Jan. 12th the ladies' committee will give a variety entertainment, to be preceded by a tea.

Middlesex Hospital.—On Christmas Day all the patients who were able to do so partook of turkeys or geese, plum puddings, &c. There was a monster Christmas tree in the board-room, from which each patient able to attend received a present; for those unable to leave their beds a bran-pie was provided. The wards were decorated and the patients' friends were allowed to visit them for two hours in the afternoon. In each of the children's wards there was a special Christmas tree, the one in Princess May Ward being lighted by electricity.

Brompton Hospital.—The Christmas festivities at this institution gave, as in many former years, great pleasure to the inmates and were as successful as willing hearts and hands could desire. The various wards and galleries were elegantly decorated by the sisters and nurses with coloured lights, mottoes, and evergreens. The creature comforts included turkeys, with port wine, oranges, and tobacco. During the festive season a Christmas tree and a concert were given.

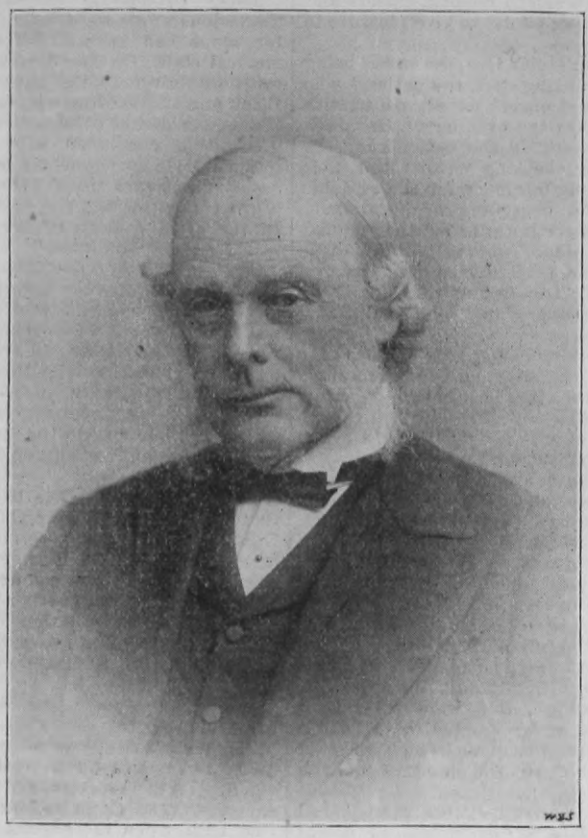
Paddington-green Children's Hospital.—The Christmas treat and entertainments to the little patients in this hospital were given on the 6th inst. at 4 o'clock. The wards were tastefully decorated with coloured ribbons, &c., by the matron and nurses. A Punch-and-Judy show was provided in one ward and a lantern display in the other. Following this the large cracker twelve feet long, filled with toys, was "pulled" and the toys were distributed amongst the children. The number of patients then in the wards was 37. The parents took tea with the children on Christmas Day.

Royal Orthopædic Hospital.—As usual at this season, the various wards were decorated for Christmas, the material for which had been kindly supplied by a member of the medical staff. On Tuesday evening, Dec. 22nd, an entertainment was given to the patients and nurses by the Tudor Black and White Minstrels, under the direction of Mr. W. H. Harris, consisting of choruses, songs, banjo solos, &c. The programme concluded with a Christmas carol, rendered in good style by the whole troupe. On Christmas Day each patient received a present through the kindness of a member of the committee and the usual Christmas fare was provided. In the evening the patients met together in the Victoria ward and had "high tea."

National Hospital for Diseases of the Heart, Soho-square.—On Christmas Eve an entertainment for the patients was given in the women's ward. Tea was given in the day ward. The room was decorated with holly, mistletoe, and chrysanthemums. At one end a small stage was placed on which Beauty and the Beast, the merchant, the wicked sisters, and the Fairy Silver-star duly appeared. This was preceded by songs, recitations, and dances. Christmas carols were admirably sung by the St. Anne's choristers. Proceedings were for a short time interrupted by the arrival of Father Christmas.

London Hospital.—The patients in the London Hospital thoroughly enjoyed their Christmas. Before daybreak on Dec. 25th the nurses bore fairy lamps round the wards and sang carols. As soon as breakfast had been finished Father Christmas (one of the medical staff) made a joyous progress through the wards, bringing in his train a much appreciated and valuable distribution of gifts. Warm clothing for nearly all, knives, books, and other small presents and toys for the children had been freely provided, and were most gratefully appreciated by the poor patients to whom they were given. The wants of these sufferers are well known to the sisters and none were left out. The patients' friends were specially admitted from 2 P.M. to 3.30 P.M., and at 4 P.M. tastefully arranged teas were provided. From then onwards to 8 30 P.M. happiness reigned supreme. The Christmas festivities concluded on Monday, Dec. 28th, when the annual Christmas trees were provided in Queen and Beatrice wards.

East London Hospital for Children, Shadwell.—The usual Christmas entertainment for the in-patients was held at the Children's Hospital, Shadwell, E., on Dec. 30th, when a large number of subscribers and friends of the charity were present. The wards were tastefully decorated and were inspected by the visitors between 3 P.M. and 4 P.M. A Punch and Judy show and two very large Christmas trees formed the chief items in the programme and afforded the greatest pleasure to the children. During the afternoon a selection of popular airs was performed by a military band.



St. Thomas's Hospital.—All the wards were prettily decorated with festoons of holly and evergreens and gay with artistic coloured drapings, Chinese lanterns, and fairy lights. On Christmas Day the patients' fare consisted of ribs of English beef, Christmas pudding, and ale for those able to take it. Pipes and tobacco were supplied for the men. Each patient was permitted to invite one friend to tea with him or her. On Boxing Day the matron was "at home" in the Nightingale Home at 4.45 P.M. At 6 P.M. a band of the nurses, led by the Home Sister, went from ward to ward singing Christmas carols. On the other days there were various musical entertainments given in the different wards by residents in the hospital and their friends. On New Year's Eve the Christmas tree entertainment was held in the Children's Ward (Victoria). This ward is for children under six years of age, but on this day the sister invited all the older children.

University College Hospital.—The Christmas entertainment to the patients at this hospital was given on Dec. 30th, the cost of the entertainment being defrayed out of funds raised by means of a special appeal made to the members of the staff, the committee, and supporters of the charity. The children's and other wards were prettily decorated and illuminated. After tea there was a distribution of toys and other things, and there was a presentation to each patient of a parcel of warm clothing. In the course of the evening a concert was given.

SIR JOSEPH LISTER: THE FIRST MEDICAL PEER.

WE have pleasure in presenting to our readers a portrait of Sir Joseph Lister, the first medical peer. Sir Joseph Lister, Bart, President of the Royal Society, was born in 1827, and educated at the University of London, where he took the degree of B.A. in 1847 and M.B. in 1852, in which year he also became F.R.C.S. Eng. He was appointed Regius Professor of Surgery in the University of Glasgow and later Professor of Clinical Surgery in the University of Edinburgh, taking the degrees of F.R.C.S. Ed. in 1855 and F.F.P.S. Glasg. in 1860. Since these dates the following honours have been awarded him: — F.R.S. Lond. and Edin., LL.D. Edin., M.D. (*hon. caus.*) Dub., LL.D. Glasg., D.C.L. Oxon., LL.D. Cantab., M.D. (*hon. caus.*) Würzburg, and M.D. (*hon. caus.*) Bologna. In 1880 Sir Joseph Lister received the Royal Society's medal in recognition of his magnificent discoveries in scientific medicine, and in 1883 he was created a baronet. In 1897 he becomes the first medical peer, the honour now done him by Her Majesty being received with unanimous applause by the whole country. In the spring of 1896 we wrote as follows upon this point:—"It would have afforded us the greatest satisfaction and pleasure ..... if the recent list of peers among the Birthday Honours had included the name of one whose services to the nation and to humanity in the introduction of antiseptic surgery have received universal recognition. Such services are indeed beyond reward, but the admission of the President of the Royal Society ..... would add lustre to the peerage. It is from such men that the second estate of the realm should be reinforced if, as it should, it is to contain the real nobility of our land." Sir Joseph Lister married a daughter of James Syme, the celebrated Edinburgh surgeon, but has no issue. Lady Lister died in 1893.

SIR JOSEPH LISTER: THE FIRST MEDICAL PEER.

SPECIAL ADDRESS OF THE COMMITTEE OF THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND:

INVITATION TO FELLOWS OF THE COLLEGE TO JOIN THE ASSOCIATION AND TAKE AN ACTIVE PART IN FORWARDING ITS OBJECTS.

WE have been desired by the Committee of the Association of Fellows of the Royal College of Surgeons of England to publish the following address to the Fellows of the College:—

On the Fellows of the College at present devolves the election of the governing body and consequently the control of the policy and work of the institution. Since this control, limited as it is, was conferred in 1843, when the order of Fellows was instituted, it can be claimed with satisfaction that in important particulars the Fellows have widened the policy, improved the work, increased the utility, and advanced the development of the College.

During the first thirty years of this control none of these results became apparent, but during that time the recognition of existing abuses and imperfections was forming and growing—the necessary preliminary of all improvement. During the last twenty years several distinct advances and definite improvements have been effected, some of which have come from without, the result of concomitant advances in professional and public requirements—as, for instance, the gradual improvement in our system of education and methods of examination, in which we have played rather a passive than an active part; but others influencing our collegiate vitality and activity have arisen within the College and are distinctly due to our exercise of our electoral functions and to the more or less consistent selection of members of Council pledged to promote those advances. Other factors than the desire to attain these objects often interfere, such as the elements of personal and hospital influence, and to that extent our course has been wavering and inconstant.

Among the advances may be mentioned the institution of the annual general meeting of Fellows and Members and of the annual report of the Council submitted to that meeting; the provision made for extraordinary general meetings; the use of voting papers at the annual election of members of Council, and, more recently, the simplification of the rules originally framed by the Council for their distribution and return; and the institution of separate half-yearly meetings of the Fellows for consultative purposes, by all of which advances the Council is brought into touch with its constituency, free discussion of interesting topics is elicited, and moral support afforded in matters of doubt and difficulty, such as the admission of women to its diplomas. A degree of vitality and of communion of thought and interest has thus been imparted to the whole collegiate body corporate which before was entirely wanting.

The policy which has effected these improvements and advances found its expression and the force of systematic action in the formation of the Fellows' Association in 1884, and since its organisation the association has systematically and undeviatingly promoted such improvements with no slight measure of success, and has resolutely supported the maintenance of concessions from the Council to the Fellows and Members whenever such concessions appeared or

Hosted by Google

actually were in danger of being withdrawn. The work already done the association considers but as part of a consistent whole, and the advances already secured but as stages to a definite goal. That goal is the embodiment in a new Charter of the concessions to the Fellows and Members by the Council and such other provisions as may be settled by the Council and the constituency.

One effect of the concessions which the association has been instrumental in securing for the Fellows from the Council has been the growth of opinion among the Fellows in favour of extending and strengthening the sense of collegiate life within the institution by giving to the Members a share in the franchise and representation on the Council. How spontaneously this feeling has spread is shown by the fact that when the Council referred for the consideration of the half-yearly meeting of Fellows in January, 1896, a resolution passed at the annual meeting of Fellows and Members in 1895, asking for the addition of eight representatives of the Members to the Council, a very large majority of the eighty-six Fellows present voted for the principle of the representation of Members of the College on the Council, and without any previous concert in any way seven members of the association spoke in favour of the concession. The subject had forced itself to the front and had to be dealt with; about half of the Council itself was known to be prepared to grant representation to the Members; and it was felt that the time had come when a long-vexed question should be set at rest in a moderate, reasonable, and practical way; and that by giving to the Members some share in the control of the body corporate, some voice in its management, and some interest in working for its welfare, the undivided attention of the Council and of the Fellows and Members would be turned to other questions of the highest importance to the College, the profession, and the public.

In consequence of the vote at the half-yearly meeting of the Fellows in January, 1896, the Council referred the matter for decision to the whole body of Fellows. The poll will close on Jan. 31st, 1897, and as many Fellows have not yet returned answers to the questions put before them the association would strongly urge on every elector who has not yet done so to vote for a concession which will harmonise all interests and greatly add to the strength, stability, power, and influence of the College both within and without the profession.

In taking up the well-known case of Mr. R. B. Anderson, whose professional rights as a Fellow and Member of the Royal College of Surgeons of England were wantonly and grossly infringed in Tobago and Trinidad, and appointing representatives on the Civil Rights Defence Committee the association has followed the lead of the Council of the College. Guided by the sense of its obligations under By-law XV., by which the Council "undertakes to protect and defend every Fellow and Member of the College who may be disturbed in the exercise and enjoyment of the rights, privileges, exemptions, and immunities acquired by him as a Fellow and Member or Member thereof," the Council appointed representatives on the Civil Rights Defence Committee in June, 1894, and its coöperation has been of signal service to Mr. Anderson. In accordance, also, with a recommendation of the Fellows at the half-yearly meeting in July, 1896, the Council instructed its representative on the General Medical Council "to forward in every way that seems feasible the objects of the Civil Rights Defence Committee in the case of Mr. R. B. Anderson." The resolution on this matter passed by the Fellows was moved by Mr. Holmes and seconded by Mr. George Jackson of Plymouth at the direct instance of the committee of the association, and marks an epoch inasmuch as it illustrates the principle that the representatives of corporations on the General Medical Council should represent effectively, not merely the views of their governing Councils, but the interests of the constituents of those bodies, and so far as the College is concerned the adoption of the resolution by the Council constitutes a precedent of the utmost value to the Fellows and Members.

Whilst warmly acknowledging the sympathy and moral support of the Council of the College in the case of Mr. Anderson, the committee of the association must point out that the only way to redress Mr. Anderson's wrongs and to re-establish his professional rights as a Fellow and Member is by a grant of money for the prosecution of his appeal to the Privy Council. The connexion of the Council with the appeal to the House of Lords, though strictly logical and demonstrable, is less obvious, and therefore the committee is not surprised that the Council has not perceived it or felt justified in voting funds for the appeal to the House of Lords. This latter appeal had to be taken up by the Civil Rights Defence Committee after the College had appointed delegates on that Committee, and in addition to that appeal to the Privy Council which the Civil Rights Defence Committee was originally formed to promote. The obligation of the Council of the College to assist in this appeal to the Privy Council for the purpose of securing the abrogation of the unjust and iniquitous decisions against Mr. Anderson, the result of judicial corruption which a Royal Commission has emphatically condemned, appears to the committee to be very clear; for, notwithstanding the opinion of its solicitor, the Council virtually decided, in June, 1894, that Mr. Anderson's rights as a Fellow and Member have been infringed, and it is only through this appeal that Mr. Anderson can be restored to his former position and become free to practise in Tobago and elsewhere and to enjoy those rights as a Fellow and Member which the Council has undertaken to defend. For this reason and because the committee recognises the obligation of the Council of the College in regard to both appeals promoted by the Civil Rights Defence Committee the committee of the association has furthered resolutions at meetings of the College asking the Council to grant a sum of money for the prosecution of Mr. Anderson's appeals. That such a grant would be a new departure and without precedent is true; but then Mr. Anderson's case is without precedent, and combines principles of so great importance, both to the public and to the profession, that its settlement by the intervention of the greatest of our professional corporations would materially add to the prestige and power of the College, and justly establish for it, in default of any action on the part of the General Medical Council, the position of a vindicator of professional rights and a leader of professional opinion.

If a favourable response to the claims of the Members of the College to representation on the Council should be given by the Fellows—and this would be assured if the Fellows who have not voted would vote for the concession—a new Charter would be required to confer such representation. It would then become necessary to embody in it the privileges and advantages which now depend only upon the good pleasure of the Council, such advantages, for instance, as the annual general meeting of Fellows and Members, the annual report of the Council, and the half yearly meetings of the Fellows. An organisation like that of the Association of Fellows must be of great service as a medium of communication with the Council, and therefore the committee earnestly invites the coöperation of all Fellows who recognise the services which the association has rendered to the Fellows during the last twelve years and who approve of the principles and policy which the association is upholding and steadily pursuing in the best interests of the College.

Signed on behalf of the Committee,

H. PERCY DUNN, Hon. Sec.

54, Wimpole-street, Dec. 30th, 1896.

THE HOUSING OF THE POOR AT MANCHESTER.

FIVE years have elapsed since we published a special report on the re-housing of the poor at Manchester.[1] We then described a somewhat bold scheme which the corporation were about to carry out, but we also indicated that the good which might reasonably be expected to accrue from this undertaking was likely to be marred by flaws in the detail of application. An area measuring 19,271 square yards where 1250 persons lived, had been condemned, together with three other smaller areas that had between them 620 inhabitants. On the largest (Oldham-street) area it was proposed to build a municipal common lodging-house after the model of those that have been so successfully erected at Glasgow; then on the other portion of the land model tenement dwellings and artisans' cottages were to be likewise erected by the municipality. Thus the city authorities were to set an example in the three forms of dwellings—the cottage, the tenement block building, and the common lodging-house.

[1] THE LANCET, July 18th, 1891.

Hosted by Google

This municipal property was to serve as a menace to all private property owners. The latter were to be told that if they did not make their houses as good in every respect as the houses, &c, owned by the municipality they would in their turn be expropriated and the town would itself erect proper dwellings. We pointed out, however, at the time that both the text of the law and the character of some of its administrators did not favour the realisation of this bold scheme. The compensation to be paid by the sanitary authority to the owners of the condemned property had to be fixed by an arbitrator, who might take into consideration not merely the actual worth of the property, but what might be its value at some future period. Further, the owners of the condemned property were at liberty to engage the most expensive counsel to defend their rights and the sanitary authorities were obliged to pay these legal advisers. Thus the costs of compensation and the legal costs were likely to be so great as to make it impossible for this municipal enterprise to succeed from a financial point of view. We protested at the time that if a house was so insanitary as to be condemned as unfit for human habitation, the owner should receive only a very small compensation. If the owners of unwholesome property could be expelled at a comparatively small cost to the sanitary authority and at some loss to themselves and if, on the other hand, the property thus municipalised was a source of income, of profit, to the town, then indeed speculators in slum property and in jerry-built houses would be seriously menaced. Honourable *bonâ-fide* private enterprise might still prosper; but that form of speculation which is founded on the extreme misery and helplessness of the poorest classes would receive a death blow. As matters now stand, however, the speculators in slum property know that the threats made against them are not likely to be realised. What with legal expenses and the compensation to be paid the execution of such threats is too costly to be carried out on anything like a large scale. Nor does it much matter if they are enforced since ample compensation is given. Thus are the owners of unwholesome house property encouraged and the purpose of the law on the housing of the poor evaded.

There was another ugly feature in the state of affairs in Manchester. Much of the poorer class of house property had passed out of the hands of its original owners—men of position and standing, who could afford to deal generously towards their tenants—and was now in the hands of former rent collectors—a harsh, rough class of self-made men. These rent collectors had lent money on mortgage to their former employers and thus became owners where they had been but collectors. Such persons are naturally opposed to sanitary reforms and at election times can exercise very strong pressure on their tenants. This has told at the municipal elections, and the interests of slum property owners is far too well represented on the town council. Such was the position of affairs described in the report we published in 1891.

Under these circumstances we are not surprised to find that the progress achieved since then has been slow and somewhat disappointing. On two of the areas condemned under the Housing of the Working Classes Acts in the years 1889–91, blocks of artisans' dwellings have been built which can house 1250 persons and 450 persons respectively. These dwellings are full of tenants. Many complaints have been made against them. They have been qualified as "barracks" and as altogether opposed to the love of privacy and independence and to the customs and tastes of the Manchester population, but the fact remains that the tenements are let easily and that many persons are waiting impatiently for vacancies so as to come into these block buildings. Nevertheless these dwellings do not pay, and this financial failure is attributed by most of the electors to blundering or perhaps to jobbery on the part of the town council. The real fault, however, rests with the law and with the consequent excessive compensations and legal costs that had to be paid so as to clear the land of its former owners. This has not been sufficiently explained to the Manchester electors. Indeed, one of the most eminent town councillors was not re-elected at the last elections principally because he neglected to give sufficient information to his constituents.

Discouraged by the little success which has met the building of tenement houses the town council has, for the moment, abandoned the project of building a common lodging-house. Nor has any other large scheme been brought forward. There are many areas remaining that should be condemned, but the town council now seems afraid to take up the subject. For the moment, the policy seems to be that of proceeding very slowly. Thus it is thought to avoid the necessity of re-constructing in the immediate neighbourhood of condemned dwellings. This, it is urged, is not necessary, unless a large number of persons are simultaneously driven out of their homes, because many of the poor go of their own accord to live in the outskirts of the town. Then, also, the well-to-do classes are migrating to the suburbs and the houses which they inhabited in central districts thus became available for a poorer class of tenants. Another, and an excellent, manner of dealing with this difficulty is to build colonies in the outlying country to be reached by cheap trams or railways; but, as this would deprive the municipality of both rate-payers and of electors, it cannot be expected that town councillors will take the initiative in such a movement.

In respect to back-to-back houses, which are so numerous in Manchester, the policy now pursued is to pull down one out of four houses so as to create a back yard. This, however, is bitterly resented by the owners of back-to-back houses; yet the result is not so much opposed to their interests as might be supposed at first sight. They lose a house, it is true, but the remaining three houses are so much improved by the possession of a back yard and the possibility of through ventilation, that an augumentation of rent naturally follows. Then it is the turn of the tenants to complain. Hence hostility is created against the town council, either amongst the owners or the occupiers, and this is another reason for proceeding slowly. All these circumstances mitigate sadly against the cause of sanitary reforms. It is questionable, also, whether it is wise to improve these back-to-back houses. That they are bad in principle admits of no doubt. Also it must be noted that most of them are very old. They overcrowd the site on which they are built. They stand on bare ground, the floors are damp and cold, and the walls and fittings are dilapidated. To improve is, perhaps, to grant a new lease of life to property of a character that should not be allowed to exist in so great, wealthy, and prosperous a town. Better by far secure the condemnation of entire areas of this bad, unwholesome property, pull everything down, and build anew according to modern sanitary principles. But in the present frame of mind of the Mnachester Town Council and perhaps also of the Manchester electorate there is little or no chance that such sweeping measures will meet with approval. The law offers good excuse for deferring any such action. If slums cannot be pulled down and sanitary dwellings erected in their stead without imposing a permanent burden on the ratepayers, the Housing of the Working Classes Act is likely to remain a dead letter. But more light is required on this subject. Some statement should be issued setting forth what the property in the condemned areas was really worth and what was actually paid in legal costs and in compensation. Nor does it seem fair that the value of slum property should be estimated by the amount of rent paid by the tenants. It is notorious that the rents paid by the poor are exorbitant and altogether in excess of the accommodation they receive. In a respectable middle-class house or villa, the same amount of accommodation, the same cubic space, can be rented for half or a quarter the price. The value of slum property should not be based on the number of tenants who can be crowded into a small space; this would be the offering of a premium to overcrowding. It would be more equitable to take as a standard a good house in a well-to-do quarter and calculate how many cubic feet of internal space is given. If the rent of this good, high-class house is £50 a year, and if the house in the condemned area contains only half the cubic space, then its value should be estimated at £25 a year. There should be a costless method of ascertaining the value of slum property. If the method just suggested is not thought practical then a radius might be drawn round the condemned area. This radius should comprise a district where the value of house property is proportionately the same or where the price of the land is the same. Then, measuring the cubic capacity of both the high-class and low-class dwellings within this radius, by comparing them with the total rental, it could be ascertained what was the average rental value per cubic foot of internal space of the houses in the district. Subsequently it would only be necessary to measure the cubic capacity of the houses in the condemned area to ascertain what should be their rent value according to the average of the district. Compensation estimated at so many years' purchase would

be given in keeping with the result of this measurement. There would be no need of arbitration. Each owner would receive the average value of house space in his neighbourhood. If, as would undoubtedly often be the case, this sum represented less than he had been in the habit of extorting from his helpless, poor, overcrowded tenants, such an unwholesome condition of things need not be taken into consideration by the law. Because unscrupulous slum-property owners overcrowd their houses and overcharge their tenants, that is no reason why the community at large should be taxed to compensate them for these extortions. The public can only be called upon to pay the just value of the property which for the public good is about to be destroyed. That just value can be ascertained by establishing a comparison with surrounding property which is not slum-property. To pay more than this renders sanitary improvement difficult, if not impossible, and offers a premium to those who exploit the extreme poor and cause them to crowd together in unwholesome and immoral surroundings.

THE TOMB OF LOUIS PASTEUR.

LAST week we published an account of the imposing ceremony of the removal of the remains of M. Pasteur to their final resting-place at the Pasteur Institute. This week we are able to present to our readers a description of the tomb and, through the kindness of Monsieur J. B. Pasteur, a reproduction of a photograph of the mausoleum of the great French *savant*. This tomb ought to be visited by every medical man who has an opportunity of doing so, not only on account of Pasteur's great services rendered, directly and indirectly, to medicine and surgery; not only on account of the great interest attached to a visit to the laboratories of the Institute, which may be made at the same time, but because the mausoleum is well worth seeing as a beautiful work of art, exquisite in taste and design and perfect in the finish of the workmanship. The Pasteur Institute is an imposing building situated in its own grounds in the Rue Dutot, but as it may not be easy for those to whom Paris is not well known to find it the best plan is to drive there; a carriage from the Place de la Concorde will reach it in about half an hour.

The mausoleum is built at the end of a long corridor in the Institute and is shut off by magnificent gates of wrought iron. Before describing it, it is interesting to note that it was built by the Pasteur family, and Monsieur J. B. Pasteur, the son of the great *savant*, suggested as a model the well-known tomb of Galla Placidia at Ravenna, which he had visited in the course of his travels in Italy.

This tomb was built about 440 by the Christian Empress Placidia, the daughter of Theodosius the Great. It is in the form of a Latin cross 49 ft. long and 41 ft. broad, and we may refer to it in some detail to show how it inspired the architect of Pasteur's tomb, Monsieur Girault. The interior of Placidia's tomb is covered by mosaics, on a blue ground. Above the entrance are garlands of fruit and foliage; and in the dome the symbols of the Evangelists. In the four arches which support the dome are figures of eight apostles, and between them is seen the familiar representation in mosaics of doves drinking out of a vase. Under the vaulting of the right and left transept are the other apostles and, between them, stags drinking at a spring in the midst of golden foliage. There are also designs in mosaic of branches of vines; and two subjects, full of grace and dignity, the *chef-d'œuvres* of Christian art in the fifth century, the first representing the Good Shepherd with His sheep and the second representing the triumph of the Christian faith. The altar is constructed of oriental onyx and behind it is the large marble sarcophagus which was at one time enriched with plates of silver.

Turning now to the Pasteur mausoleum, we find the archway over the gates decorated in mosaic with irises on a gold ground, and there is also the simple inscription—"*Ici repose Pasteur*," and on either side of it the dates of his birth and death—1822 1895. Passing through the gates, the crypt is approached by a flight of nine steps of white statuary marble. The pavement of the crypt is of marble mosaic on which are represented large wreaths of laurel. The crypt is formed by four arches which support a cupola, and in the centre is placed the sarcophagus, which is carved out of a single block of dark-green porphyry. The arches are supported on four groups each of three columns, two of green porphyry and one of red, with Byzantine capitals of white marble. The walls of the crypt are lined with pavonazza, a cream-coloured marble richly veined in black, and above it are beautifully executed mosaics. On the marble which fills the arches on the right and left are inscriptions indicating Pasteur's discoveries in historical order as follows:—

1848.
Dyssymétrie Moléculaire.
1857.
Fermentations.
1862.
Générations dites Spontanées.
1863.
Études sur le Vin.
1865.
Maladies des Vers à soie.
1871.
Études sur la Bière.
1877.
Maladies Virulentes.
1880.
Virus Vaccins.
1886.
Prophylaxie de la Rage.

Beyond the sarcophagus is an apsidal chapel containing an altar of white marble enclosed by a balustrade of the same material. Above the staircase is the following inscription from the oration delivered at the reception of Pasteur into the Academy of Science: "Heureux celui qui porte en soi un dieu, un idéal de beauté, et qui lui obéit—idéal de l'art, idéal de la science, idéal de la patrie, idéal des vertus de l'Évangile." In the apse is another inscription containing the name of the architect and other interesting particulars: "Ce monument fut élevé en MDCCCXCVI. à la mémoire de Pasteur par la piété de sa veuve et de ses enfants. Charles Louis Girault composa l'architecture et la décoration; il dirigea les travaux. Luc Olivier Merson dessina les figures de la coupole. Auguste Guilbert Martin exécuta les mosaïques."

In the mosaics are representations of fowls, cattle, sheep, and dogs, indicating Pasteur's researches on chicken cholera and attenuation of virus, on anthrax, on *clavelée* or sheep-pox, and on rabies. There are also beautiful designs of hops, vines, and mulberry trees with silkworms and moths, illustrating respectively his researches on the so-called diseases of beer and wine and on the silkworm disease. Pasteur was a devout Roman Catholic, and the religious side of his character is indicated in the mosaics by angelic figures of Faith, Hope, Charity, and Science, and, above the altar, by the figure of a dove descending, representing the Holy Spirit, and on either side the Greek letters A and Ω. At the top of the cupola light is admitted through slabs of oriental onyx.

Such is the magnificent resting-place of Louis Pasteur, and it was a happy idea that this tomb should be placed where his successors carry on his great work and where students from all parts of the world may be reminded of the example he set of a life of untiring devotion to science and humanity.

PROVIDENT DISPENSARIES AND THEIR CLAIM ON THE MEDICAL PROFESSION.

A SPECIAL meeting of the Council of the Charity Organisation Society was held on Jan. 4th at the Royal United Service Institute, Whitehall, S.W., when Mr. C. H. WARREN (secretary of the Metropolitan Provident Medical Association) read a paper on "Provident Dispensaries and their Claim on the Medical Profession." There was a good attendance.

The Earl of STAMFORD, who presided, in introducing Mr. C. H. Warren said that there had been a feeling in the medical profession against certain abuses which had arisen in connexion with medical clubs. All were agreed that the provident dispensary system was a thoroughly good one and tended in the direction of thrift and self-help.

Mr. C. H. WARREN said coöperation between provident dispensaries and hospitals might be termed the root idea of all writers and authorities on these questions for many years past. As a means towards this end an association was established some sixteen years ago. One of its objects had been and still was: "To coöperate with the governing bodies of the metropolitan hospitals in order that they might be relieved of the large number of ordinary cases of illness which at present overcrowd their out-patient departments, and also have referred to them from the provident branches cases which required special hospital treatment or were suitable for clinical instruction." How far this coöperation had been attained might be gathered from the following facts.

Hosted by Google

When the association was started there were, so far as he had been able to ascertain, about forty provident dispensaries or medical clubs worked on the provident system in the metropolis. There were now fifty-six, and in addition some of the old free dispensaries had adopted a semi provident or part-pay principle. Of these fifty-six it was scarcely possible to point to a really successful provident dispensary in the neighbourhood of a great general hospital or free dispensary. What was more, on two or three occasions provident dispensaries had been closed because of the severe competition of neighbouring hospitals or free institutions. The abuses of the hospitals' out-patient departments might be classed under two heads. First, persons were admitted who were well able to pay something for their medical treatment, and secondly, slight cases of illness were admitted which were not proper cases for hospital treatment at all, and could be as well treated at the patients' homes or in a medical man's surgery. To remedy these abuses there have been some feeble attempts on the part of the hospital authorities. In many of the hospitals the attention of the out-patients was directed, by means of posters, cards, &c., to the existence in the neighbourhood of provident dispensaries, but the numbers in the out-patient departments were not in consequence reduced.

At the Royal Free Hospital a more systematic attempt was being made in connexion with the Charity Organisation Society to deal with the matter. Here an almoner had been at work for some time inquiring into the position and circumstances of persons in the out-patient departments, with a view of transferring suitable cases to provident institutions. In furtherance of this work a provident institution has been established in Islington on the medical club system; that was, without dispensary premises, the patients attending at the medical men's surgeries when advice or medicine was required and receiving home treatment when necessary. Each case sent from the hospital was followed up and visited, and of the total cases sent about 17 per cent. had been enrolled members of the provident institutions and of the neighbouring Bloomsbury Provident Dispensary. In other hospitals the plan had been adopted of admitting only a certain number of new cases each day. So far as these efforts went they might be considered perfectly satisfactory, but he did not think the same could be said of the system of charging a fee to out-patients, which was the practice in one or two hospitals. This appeared to aggravate the evil. The neediest, and frequently most deserving cases, had to pay for what should be charity, and the well-to-do were encouraged to come under the impression that they were paying for the treatment they received. The great defect of these schemes seemed to be that they began too late—they were attempted cures rather than preventives. What was required was to keep unsuitable cases out of the hospitals rather than try to weed them out after the mischief was done. He believed one condition essential to the success of any scheme for reforming the out-patient departments was the abolition of the letter system as at present understood, and when that was accomplished to admit cases for out-patient treatment only on the recommendation of a medical man who knew the case, in connexion with some organised association, or in private practice. Something on these lines had been recently attempted by coöperation between the Metropolitan Provident Medical Association and the Hospital Saturday Fund. The results of the experiment for the first two months, from Aug. 1st to Sept. 30th, was that 464 applicants were supplied with certificate forms. Of these only 226 were returned with the medical man's opinion; the remaining 238 applicants for some reason or other did not see fit to submit themselves for examination. Of the 226 cases examined 124 were sent to chest hospitals, 74 were treated at the various dispensaries of the association, and 28 were considered suitable for treatment at general hospitals. Taking the total number of those who applied for hospital letters (464) only 152 were considered proper cases for hospital treatment. The remaining 68 per cent. had been kept away from the hospitals because of their unsuitability, and for those treated at the dispensaries the medical men had received proper remuneration. In addition to this these people had been brought into touch with provident institutions. The success or failure of such an arrangement must necessarily be judged from three points of view—that of the hospital, the medical men, and the persons treated. The numbers dealt with were at present so insignificant compared with the million or more cases which annually crowded into the out-patient departments that it was too early to get an opinion from the hospital point of view. From the medical men concerned he had received nothing but praise of the arrangements. Up to the present the provident dispensary movement had been only partially successful; one of the reasons was the lack of support from the medical profession. In the out-patient departments of hospitals persons were admitted for free treatment who were well able to pay for their medical attendance. A similar objection had been raised in the case of provident dispensaries. He was not prepared to recommend a general wage limit, which must be determined to a large extent by the district in which the dispensary is situated, and also by the scale of payments charged to members. A reasonable view of this matter appeared to have been taken by a committee under the chairmanship of Sir Spencer Wells in 1887, which consisted of twenty-five medical men and eleven laymen. To carry out this principle of insurance this committee made the following recommendations:—That all candidates for membership should be approved by the medical officer under whom they wished to be registered. That they should be free to benefit in four weeks from the date of joining. That the rates of contribution should be: single persons, male and female, 6*d*. per month; man and wife without children, 1*s*. per month; man and wife with children, 10*d*. per month; children under sixteen years of age, 3*d*. per month each, not charging for more than four in one family. That applicants for membership must make a declaration that their average earnings do not exceed, in the case of a single person, or man and wife, 30*s*. per week, or of a family 40*s*. per week. The committee were of opinion that provident dispensaries established with this scale of charges and wage-limits would be supported by the medical profession and would meet the wants of the working classes. Speaking of the competition which the provident dispensaries had to meet from the medical aid societies of insurance companies, he said the principles underlying them were totally different. The medical aid society was a business concern carried on for purposes of profit, which was gained at the expense of the medical man, and without any of the safeguards attaching to the provident dispensary. In conclusion Mr. Warren said the difficulties surrounding medical practice had been largely created and were being perpetuated by the want of union in the profession, and it was only by a strong combination that these difficulties would be overcome.

Mr. G. H. BROADBENT said he came to the meeting with a verdict adverse to the practice outlined in the paper. In Manchester, where a Provident Dispensary Association had been established for over twenty-one years to promote the very objects indicated in the paper, the system had proved to be a vast abuse.

Mr. T. R. ATKINSON expressed the belief that it was the medical profession which was to blame for the wrecking of the provident system in Manchester by their apathy.

Dr. ALDERSON spoke of the abuse of medical aid societies.

Mr. A. BOUSFIELD (chairman of the Metropolitan Provident Medical Association) said he was very much in favour of properly conducted provident dispensaries within the reach of the working classes of London, and if a very slight reform took place he believed the system would admirably work in with that of the hospitals. He thought that provident institutions should be largely under the control of medical men, but difficulties would certainly be created unless all parties combined.

Dr. GUSTAVE MICHAEL strongly advocated the principles of the provident system. The insurance system aided the medical man in many ways; a wage limit was fixed, and no man was admitted unless he had been examined and passed by a medical man whom he had himself chosen. All medical matters, too, came before the medical men who were on the committee. All the profits went to the medical man, the subscriptions being divided between him and the working of the institution.

Dr. O. F. WUNDERLICH said it was the managers of hospitals who were to blame for the abuse which obtained there, and if they had to pay for the medical attendance which was given they would soon see that the abuse was put an end to.

Miss PLACE gave her experience as secretary of a provident dispensary.

Dr. BARKWELL advised medical men to have nothing whatever to do with any association where the laity sat upon a committee and dictated to them.

Dr. F. J. L. HART had every sympathy with the terms of the address, but he asked whether the system advocated was to be a compromise or whether medical men were to manage

Hosted by Google

their own affairs. He was sure they could do so if there was more unanimity among them.

Mr. GEORGE BROWN thought that the Charity Organisation Society was entitled to the thanks of the medical profession for convening a meeting in order that a matter of the most pressing importance to the profession and the public might be discussed. It might do a great deal to crystallise the subject and bring about a proper solution. The organisation, however, had not fulfilled the hopes which the profession had reposed in them when the subject was taken up. It was hoped that they would succeed in taking away patients who abused the out-patients' department of hospitals, and if possible put them into the surgeries of the private medical man. But this they had not done. He maintained that the medical profession must have absolute veto over the admission of patients into the provident dispensary. He objected to several remarks made by the writer of the address, disagreeing with the writer's idea of proper remuneration, and maintaining that patients should be taught to know that the medical men were not being adequately paid for their services.

After some remarks from Mr. ATKINSON, who favoured the general principles of the address,

Mr. TIMOTHY HOLMES explained that the provident dispensary movement set forth in the address was started, he believed, by Sir George Trevelyan and his friends a great number of years ago with the object of providing the working class with proper medical attendance on such terms as was possible and to give the greatest remuneration possible to the medical attendant. The Provident Medical Aid Association had kept the object in view, and he had no hesitation in saying that the chief obstacle of raising the standard was the action of medical men themselves in underselling each other. Supposing the remuneration at one dispensary was fixed at 6*d*., another dispensary would be started in the next street where the remuneration would be 4*d*. This was what the profession came to when it professed to manage its own affairs. If medical men would fall more generally into the ranks of the provident association and would admit the laity to a fair share of the management, he believed that they would find that they would get such remuneration as was possible out of the class of persons for whom the association existed, and they might see for themselves that no persons above that class were admitted into the association. He believed the plan proposed was entirely a fair one, and if carried out methodically it would mean a satisfactory solution of the problem, always with one most material stipulation—namely, that some reasonable arrangement could be made with the out-patient departments of hospitals. That would be possible if the medical profession and the laity would work honourably together.

Other speakers continued the discussion.

THE PLAGUE IN BOMBAY.

INFORMATION under date of Nov. 20th from Bombay brings news of the state of that city from the point of view of one of the oldest medical practitioners addressed to a friend in England. He says: "You are well out of Bombay just now, for we have fallen on troublous times. Our grand system of sewerage, the working of which the engineers refused to verify in the cocksureness that it was profoundly, and even scientifically, perfect, has landed us in an outbreak of plague. The epidemic has been with us for eight weeks and continues. Twenty attacks were reported yesterday. The plague and an increase of remittent fever and of respiratory diseases—all germ diseases—came together. The two latter have nearly doubled their usual mortality. Now, as these three have risen up and are progressing together and arise from the same cause—viz., a putrid atmosphere—you will see at once that they all come from the same source. The poison germs that enter the blood in plague, that enter the lungs in pulmonary diseases, and that enter the system in remittent fever, may all be distinctive germs, but they are bred in the same laboratory—the sewers and house connexions. All this is so plain to you that I need not say one word more. If microscopes are required to hunt for the bacilli they should be applied to the gaseous escapements from the sewers, drains, and house connexions. More than a fourth of our population have bolted from Bombay and we are all suffering from loss of business. And, lastly, there is a great famine looming in the distance." The state of the sewers and drains referred to has been the subject of much desultory inquiry and discussion in the corporation of Bombay, but so far the science of the work has received but scanty recognition from that body. This excites little surprise among those who know the quality of the average member and the method of appointing him. An Indian municipality is neither better nor worse than the similar governing bodies in England of fifty or sixty years ago, but in sanitary matters the results of mismanagement are much more palpable and severe in India than in England for reasons which may be easily explained.

Bombay has a mean temperature of 79·13° F., which is 30° higher than that of London. Its maximum recorded temperature is 100·2, with a minimum of 53·3°. The mean relative humidity is 77 per cent, while that of London is 82 per cent. at mean temperature; but when the quantity of vapour in suspension of the two places is compared, the London atmosphere would contain 0·51 lb. per 1000 cubic feet, while Bombay would have 1·135 lb.

In England the temperature of main sewers is generally under 55° F., so low, in fact, as to greatly retard putrefaction; and visitors to the London sewers are often surprised at the absence of foul smells, which they usually expect to meet underground. In Bombay the lowest recorded temperature in the main sewer in the cold season was 75·2°. In the summer the water-supply enters the city at from 82° to 84°. It will therefore be no matter of surprise if the sewage should be the foulest in the whole world, or that dead organic matter, whether animal or vegetable, begins to decay immediately, and putrefaction follows rapidly in Bombay.

The difficulties of sanitary administration arise from the rapidity of decomposition of organic matter, the density of population, and the primitive habits of the people, which have never been brought in line with the necessities of a closely inhabited town having in certain wards a density of 760 per acre. In addition to the fixed population there is a constant current of immigrants coming from the mainland, mostly of the labouring class, who remain for a time to benefit by the well-paid labour of the city and who return to agricultural occupations. These people know nothing of sewers, latrines, waterworks, or conservancy regulations. They seek lodgings in the densely crowded parts of the town, and the men will often join, eight together, in the hire of a single room, ten feet square and eight feet high, in which they will sleep together with door and window-shutter closed during the rainy season. In a city with the climatic condition of Bombay, and with such a dense population, the sanitary rules should be stricter and the individual compliance with them more complete than is the case in England if the death-rate is to be kept within reasonable limits. The reverse, however, is the case and the city appears always to exist on the verge of an epidemic of some sort. The sewers were made many years ago upon English models when there was no Indian experience to go upon, and the water-supply has been increased to meet the wasteful habits of the people until, at times, the sewers will not carry the volume flowing into them. There are thus extreme fluctuations of volume of the sewer air which is expelled with every rise of the water. This air is exceedingly foul, and must of necessity always be so on account of the temperature of the sewers, and as the fundamental data for the proper ventilation of Indian sewers have not yet been properly worked out the state of the atmosphere at ground level along the line of sewers is anything but wholesome. No analysis has ever been made of the sewer gases of Bombay, although many deaths have taken place of labourers who have had to work in them.

More work and better organisation would be necessary to keep an Indian city clean and wholesome than is requisite in Europe, for reasons attributable solely to climate, and when resistance, active or passive, of the native is added the task of administration becomes herculean. The health officer and the municipal engineer are regarded with tolerance, if not with open hostility, and they are often expected to do their work without that individual aid or compliance with rule on the part of citizens which is the very foundation of successful working in Europe. There is no educational standard in an Indian municipality, and it frequently happens that in the constitution of these bodies a much greater number of men is called for than the town can furnish

Hosted by Google

of the right sort. Then follows the anomaly of an active and intelligent minority doing the work of the municipality, which they must then submit to the approval or disapproval of a very incapable majority. This will explain many of the serious errors that have been made in municipal sanitation in India, and when, as in Bombay, the corporation is averse to scientific research in matters of vital importance, such as an analysis, ventilation of sewers and drains, and other works, which for successful execution must be based on local facts and figures, the prospects of public health are anything but good. The precautions of Europeans against disease, and especially that of a contagious character, are always in danger from the interference of domestic servants who belong to the lower classes and whose ideas regarding hygiene have been little influenced by their relations with Europeans. In the preparation of food, the cleansing of vessels, the frequentation of sick persons, and in the wearing of second-hand clothing of deceased persons that ought to have been destroyed the native servant is a constant, although unconscious, source of risk, although he may all the time adhere strictly to his traditions of ceremonial purity. The Europeans, as a rule, are too careless of sanitary precautions and they often suffer in consequence of their neglect of the claims of the climate.

The wholesome influence of a good water-supply seems to have been generally impressed on the native mind, but every departure from his customary habits in other respects is met with dislike and, if it involves the least extra trouble, with hostility, which makes itself felt in municipal affairs.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 7451 births and 4634 deaths were registered during the week ending Jan. 2nd. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 19·4 to 17·0 per 1000, rose again last week to 22·3. In London the rate was 20·8 per 1000, while it averaged 23·3 in the thirty-two provincial towns. The lowest rates in these towns were 16·6 in Bradford, 16·8 in Croydon, 17·2 in Bristol, and 17·8 in Burnley; the highest rates were 29·6 in Birkenhead, 31·2 in Norwich, 31·4 in Cardiff, and 31·8 in Plymouth. The 4634 deaths included 436 which were referred to the principal zymotic diseases, against 357 and 279 in the two preceding weeks; of these, 106 resulted from whooping-cough, 97 from measles, 93 from diphtheria, 53 from scarlet fever, 47 from diarrhœa, and 40 from "fever" (principally enteric). The lowest death-rates from these diseases were recorded in Norwich, Halifax, Sunderland, and Portsmouth; and the highest rates in Cardiff, Plymouth, Gateshead, and Nottingham. The greatest mortality from measles occurred in Cardiff, Bradford, Gateshead, Nottingham, and Plymouth; from scarlet fever in Oldham; from whooping-cough in Birkenhead, Huddersfield, Nottingham, and Swansea; from "fever" in Gateshead; and from diarrhœa in Blackburn. The 93 deaths from diphtheria included 49 in London, 8 in West Ham, 8 in Cardiff, 8 in Birmingham, 4 in Sheffield, and 3 in Liverpool. No fatal case of small-pox was registered in any of the thirty-three towns. There were 3 small-pox patients in the Metropolitan Asylum Hospitals on Saturday last, the 2nd inst., all of whom had been admitted during the week. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3707, against 3971, 3868, and 3763 on the three preceding Saturdays; 271 new cases were admitted during the week, against 353, 291, and 219 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 302 and 284 in the two preceding weeks, rose again to 348 last week, but were 254 below the corrected average. The causes of 88, or 1·9 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Manchester, Leeds, Newcastle-upon-Tyne, and in eight other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Liverpool, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the five preceding weeks from 20·3 to 22·1 per 1000, further rose to 22·4 during the week ending Jan. 2nd, and slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·8 in Greenock and 19·5 in Aberdeen to 23·7 in Glasgow and 23·8 in Dundee. The 655 deaths in these towns included 60 which were referred to measles, 16 to diarrhœa, 15 to whooping-cough, 5 to scarlet fever, 4 to diphtheria, and 3 to "fever." In all, 103 deaths resulted from these principal zymotic diseases, against 95 and 106 in the two preceding weeks. These 103 deaths were equal to an annual rate of 3·5 per 1000, which was 1·2 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 37, 54, and 48 in the three preceding weeks, rose again to 60 last week, of which 44 occurred in Glasgow, 9 in Aberdeen, and 4 in Paisley. The deaths referred to whooping-cough, which had been 7 and 26 in the two preceding weeks, declined to 15 last week, and included 12 in Glasgow. The 5 fatal cases of scarlet fever showed a decline of 3 from the number in the preceding week, and included 2 in Glasgow. The deaths from diphtheria, which had been 7 and 4 in the two preceding weeks, were again 4 last week, of which 2 occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 121 and 152 in the two preceding weeks, were 151 last week, and slightly exceeded the number in the corresponding period of last year. The causes of 50, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·3 and 26·5 per 1000 in the two preceding weeks, rose again to 44·1 during the week ending Jan. 2nd. During the fourteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 27·6 per 1000, the rate during the same period being 18·1 in London and 17·8 in Edinburgh. The 296 deaths registered in Dublin during the week under notice considerably exceeded the number in the preceding week, and included 36 which were referred to the principal zymotic diseases, against 21 in each of the two preceding weeks; of these, 23 resulted from whooping-cough, 5 from measles, 4 from diarrhœa, 3 from "fever," 1 from scarlet fever, and not one either from small-pox or diphtheria. These 36 deaths were equal to an annual rate of 5·4 per 1000, the zymotic death-rate during the same period being 1·8 in London and 2·1 in Edinburgh. The fatal cases of whooping-cough, which had increased from 4 to 15 in the three preceding weeks, further rose to 23 last week, a considerably higher number than in any preceding week during the past ten years. The 5 deaths referred to measles exceeded the number recorded in any week since February, 1894, while the mortality from scarlet fever showed a further decline from that recorded in recent weeks. The 296 deaths in Dublin last week included 75 of infants under one year of age and 62 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded those registered in the preceding week. Twelve inquest cases and 9 deaths from violence were recorded; and 78, or more than a fourth, of the deaths occurred in public institutions. The causes of 23, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR-GENERAL W. NASH took over the appointment of Principal Medical Officer, Royal Victoria Hospital, Netley, from Brigade-Surgeon-Lieutenant-Colonel Fairland on the 1st inst. Surgeon-Captain R. E. Kelly is posted to Woolwich for duty, and Surgeon-Major N. Leader has assumed medical charge of the Station Hospital, Cardiff. Surgeon-Colonel R. P. Ferguson has joined at Woolwich for duty.

Surgeon-Lieutenant Howell has been placed under orders for service in India. Surgeon-Lieutenant-Colonel Henry Haldane Stokes to be Brigade-Surgeon-Lieutenant-Colonel,

Hosted by Google

vice H. T. Brown. Surgeon-Lieutenant-Colonel Reginald William Mapleton to be Brigade-Surgeon-Lieutenant-Colonel, vice J. P. Rooney, promoted. Surgeon-Lieutenant J. A. Murison is placed on temporary half-pay on account of ill-health.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major-General James Cleghorn has proceeded from Calcutta to Bombay in order to make a special report for the Indian Government upon the plague.

Surgeon-Captain G. B. Stainstreet, A.M.S., to be Personal Assistant to the Principal Medical Officer, Punjab Command, vice Surgeon-Captain J. Thomson, A.M.S., transferred to the Home Establishment. The services of Surgeon-Captain D. G. Marshall (Bengal) are replaced at the disposal of the Military Department. Surgeon-Captain J. C. S. Vaughan, Deputy Sanitary Commissioner, Western Bengal Circle, is placed on special duty in connexion with anti-cholera inoculation. Surgeon-Lieutenant E. S. Peck, on special duty under the Medical Board, is appointed to act as Deputy Sanitary Commissioner, Western Bengal Circle, during the absence, on deputation, of Surgeon-Captain J. C. S. Vaughan, or until further orders.

The Queen has approved of the following promotions:—Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels: *Bengal Establishment:* Joseph O'Brien, Alexander Crombie, and William Reed Murphy, D.S.O. *Bombay Establishment:* Randolph Caldecott. Surgeon-Majors to be Surgeon-Lieutenant-Colonels: *Bengal Establishment:* James Moorhead, Charles William Owen, C.M.G., C.I.E., and Gilbert Saunders Griffiths. *Madras Establishment:* William Alexander Lee and Montague Stokes Eyre. *Bombay Establishment:* Osborne Henry Channer, Edward William Young, and Hugh McCalman. Surgeon-Captains to be Surgeon-Majors: John Tasman Waddell Leslie, David Prain, Arthur Thomas Bown, Upendra Nath Mukerji, and William Locking Price. The Queen has approved of the transfer of the under-mentioned officers to the Half-pay List:—Brigade-Surgeon-Lieutenant-Colonel Woodforde Finden (Bengal Establishment); Surgeon-Lieutenant-Colonel Maurice Henry Smith (Madras Establishment); and Surgeon-Lieutenant-Colonel John Macgregor (Bombay Establishment). The Queen has approved of the resignation of Surgeon-Captain Townsend Wharton Shaw (Bombay Establishment).—*London Gazette.*

NAVAL MEDICAL SERVICES.

The following appointments are announced:—Fleet-Surgeon John Dudley to Yarmouth Hospital. Staff Surgeons: John D. Henwood to the *Empress of India;* Samuel W. Johnson to the *Devastation;* and Bassett C. E. P. Gunn to the *Flora*, for duty on the way home. Surgeons: Edward T. P. Eames to the *Karakatta;* Robert F. Bowie to the *Flora*, for duty on passage, and afterwards to the *Tauranga;* Arthur W. B. Livesay to the *Blenheim;* William Belt to the *Britannia;* Richard F. Bato to the *Halcyon;* and Edward Sutton to the *Wildfire.*

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant H. P. Job, 4th Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment), to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Cinque Ports (Eastern Division, Royal Artillery): Edward Charles McMurrogh Murphy, gent., to be Surgeon-Lieutenant. 2nd Cinque Ports (Eastern Division, Royal Artillery): Surgeon-Lieutenant C. Wiggins resigns his commission. *Rifle:* 1st Volunteer Battalion the Bedfordshire Regiment: John Wardle Bone to be Surgeon-Lieutenant. 3rd (Cambridgeshire) Volunteer Battalion the Suffolk Regiment: Surgeon-Major F. M. Beckett resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 1st Volunteer Battalion the East Yorkshire Regiment: Surgeon-Lieutenant-Colonel H. Thompson resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the battalion on his retirement. 2nd Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant William Frederick Brook is appointed Second Lieutenant. 1st Volunteer Battalion the King's (Shropshire Light Infantry): Francis Henry Thompson, gent., to be Surgeon-Lieutenant. 3rd Middlesex: Surgeon-Major F. Orton to be Surgeon-Lieutenant-Colonel. 2nd Volunteer Battalion the Prince of Wales's (North Staffordshire Regiment): Surgeon-Major W. G. Lowe to be Surgeon-Lieutenant-Colonel; and Surgeon-Captain H. J. Fausset to be Surgeon-Major. 1st (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): John Nairn Marshall to be Surgeon-Lieutenant.

A FRENCH CRITICISM OF THE LATE ASHANTI WAR.

Under the rubric "Revue des Guerres" Surgeon-Major of the First Class P. Grivet fills twenty pages of the *Archives de Médecine et de Pharmacie Militaires* for December with an extremely appreciative and accurate account of the second English expedition against the Ashantis. His opening sentence is to the following effect:—"After an interval of twenty years England has just renewed—in the same theatre and with the same success—the experiment of that 'doctor's war,' whereof the brilliant sanitary results, vulgarised by Inspector-General L. Colin, are so often quoted. The military and political results of that rapid campaign are already well known." With the exception of the French Gaboon, continues our friendly critic, quoting Gerville-Réache, there is no more insalubrious portion of the black continent than that which was traversed by the expedition, but thanks to the admirable management anticipative as well as current, everything went off without the slightest hitch. Surgeon-Major Grivet's commendation is doubtless as just as it is generous, for it is likewise clear that when occasion arises he is capable of apportioning blame discriminately. With reference to the serge clothing, for instance, he describes the quality as indifferent and the construction as unsuitable. The stuff wore out at the elbows and knees with disgraceful rapidity, while the stiffening that had been added to the collars and cuffs caused needless irritation of the neck and wrists. The helmets, too, were far from perfect, as they failed to protect the ears and temples. The Pasteur-Chamberland filters were by no means a success. The tripods they rested on sank into the ground when the receptacles were full, and the bougies were so fragile that, even with the greatest care, they were frequently broken in cleaning. The exhaustive way in which all the details of the expedition had been worked out beforehand seems to have somewhat surprised the French critic. Amongst other things he highly extols the tin packing cases, which were hermetically constructed in two sizes to hold 45 lb. and 60 lb. respectively. Having been carefully moulded to fit the backs and shoulders of the native carriers, they could be transported with the utmost facility. The Maconachie ration, which was frequently issued and highly esteemed, likewise comes in for special mention. In conclusion Surgeon-Major Grivet expresses his surprise that a complete history of these successful operations has not as yet emanated from our army medical headquarters. It is certainly a subject for regret that the medical history of the late Ashanti expedition has not so far seen the light, but if we consider the extremely exiguous clerical staff at the disposal of the Director-General, the wonder is that reports of this description, when at length they do appear, should be so admirably compiled and edited.

DEATHS IN THE SERVICES.

Surgeon-Lieutenant-Colonel Alexander McGregor, I.M.S. (retired), recently from the effects of disease originally contracted in India. He entered the Indian Medical Service in 1872 as assistant surgeon, was promoted Surgeon-Major in 1884, and Surgeon-Lieutenant-Colonel in 1892. He served with the Punjab Frontier Force in medical charge of the 4th Punjab Cavalry. He was subsequently in medical charge of the following regiments:—5th Bengal Cavalry, at Bareilly; 2nd Goorkhas, at Dehra Doon; and the 8th Bengal Cavalry, at Nowgong. On the occurrence of the Black Mountain expedition he was selected for the medical charge of the Native Field Hospital, and at the termination of the campaign was mentioned in despatches and received the medal awarded for the expedition.

ENTERIC FEVER AT QUETTA.

We regret to learn that there has been a recrudescence of enteric fever among the European troops stationed at Quetta, our strategic post situated at an altitude of over 5000 ft. above the sea level near the entrance to the Bolan Pass in Beloochistan. The outbreak appears to be strictly confined to the garrison, not one case having occurred outside the fortifications. The total mortality from typhoid fever up to November amounted to twenty-three, distributed as follows: Ten deaths in the Lancashire Fusiliers, seven in the Border Regiment, and six, including one officer, in the Royal

Hosted by Google

Artillery. At the time of the latest report eight fresh cases of enteric fever had been admitted to the Quetta Hospital.

ARMY BOOTS.

"Marcellus," in his Military Notes in a Worcester contemporary this week, says: "The Mayor of Droitwich, Mr. H. Shirley Jones, has offered a pair of prize army boots to each of the two best recruits of the Droitwich company of volunteers." A medical officer of the battalion describes the boots to our contemporary, the *Droitwich Guardian*, in enthusiastic terms. There is not a point in military equipment of more importance to the soldier than his boots, and if Mr. H. Shirley Jones (who is a member of the medical profession), while encouraging the shooting of the Droitwich volunteers, can give the War Office authorities an improved pattern of boot he will do well.

NEW YEAR HONOURS FOR THE SERVICES.

Among the names in the list of New Year Honours will be noticed those of the Hon. William Raymond Kynsey, C.M.G., who received the honour of knighthood, and of Deputy-Surgeon Charles Benjamin Mosse, who has been made a Companion of the Order of St. Michael and St. George. The Hon. Sir William Raymond Kynsey is a retired Surgeon-Captain in the Army, a member of the Legislative Council of Ceylon, and Inspector-General of Hospitals and Asylums in that island. Deputy-Surgeon-General Charles Benjamin Mosse, C.B., C.M.G., is the superintending medical officer of Jamaica.

THE "ADMIRALTY AND HORSE GUARDS GAZETTE."

Our contemporary the *Admiralty and Horse Guards Gazette* announces that its first number for the New Year has been reduced in price to 3*d*., while the size, form, and scope of the paper remain as hitherto. In the new number there is an interesting leading article in reply to a letter from Mr. Maxim, in which he defends himself against a charge of egotism in connexion with his recent lecture on "The Automatic System of Firearms, its History and Development."

MOVEMENTS OF TROOPS.

Notification has been received intimating the departure of the transport *Britannia* from Bombay and the transport *Cephalonia* from China and Straits Settlements with the under-mentioned invalids for Netley: *Britannia*, 145; *Cephalonia*—from China 33, and from Straits Settlements 12, making a total of 45.

Correspondence.

"Audi alteram partem."

A QUESTION OF COPYRIGHT AND A QUESTION OF COURTESY.

To the Editors of THE LANCET.

SIRS,—I would be pleased to have an expression through you from the members of the medical profession as to the relations of the lay publishing firms of medical journals and the profession. The request is suggested by the fact that Messrs. Wm. Wood and Co. of New York refuse to permit the editors of "The American Year-book of Medicine and Surgery" to use in their abstracts of medical progress articles and illustrations first printed in the *Medical Record* and the *American Journal of Obstetrics*. This decision seems to me to be wrong for the following reasons:—

1. It prevents the dissemination of medical knowledge. The "Year-book" condenses, systematises, and criticises the year's medical work in a shorter space and more permanent manner than the journals and has thousands of readers no single journal can claim or hope to reach. Every physician writes and publishes articles in order that every member of the profession may, if possible, learn of his work and that science and progress may thus be furthered and humanity benefited. To interfere with such dissemination of our literature in reputable publications is, I think, discourteous and unjust to the profession and an injury to medical science.

2. This injustice and injury to medicine become all the more striking when physicians do not receive a cent of pay for contributions, from the publication of which the lay-publisher is supposed to make considerable financial profit.

3. No other publishers in the world, not even those who pay authors for their contributions, have in the least objected to our reproduction of quotations, abstracts, and illustrations from their journals.

Does the medical profession wish to limit the dissemination of contributions to medical science by such an exclusion of them on the part of publishers from reputable publications? *Is this literature the property of the author and of the profession or not?* Does your gift of it to a journal make it the private property of the publishers of that journal? Is it not rather a loan for temporary use only? Will you not hereafter demand that there be printed with your article a statement that the right of abstracting the text or reproducing illustrations is guaranteed?

I am, Sirs, sincerely yours,
GEO. M. GOULD.

South Seventeenth-street, Philadelphia, Pa., Dec., 1896.

*** As far as British copyright is concerned, Dr. Gould's letter confuses questions of courtesy with questions of law. Unless author and editor or publisher or proprietor or any necessary combination of them contract themselves out of its operation their mutual relations are definitely regulated by law. The literary property upon publication becomes so vested that the author cannot republish or sanction re-issue of the work without the proprietor's permission, nor can the proprietor do so without the author's permission. By courtesy on each side or by special business arrangement all proper facilities for re-issue are usually given.—ED. L.

"THE TRAINING OF NURSES IN RELATION TO REGISTRATION."

To the Editors of THE LANCET.

SIRS,—I note in THE LANCET of Jan. 2nd that, in light of the facts placed before you by Dr. Outterson Wood, you reverse the verdict previously given in favour of those who are opposed to the admission of certificated asylum attendants to the Royal British Nurses' Association. I trust you will permit me, with your usual impartiality, to criticise the facts in question and Dr. Wood's method of handling them. In stating that the feeling of anxiety with regard to his scheme is limited to a small minority Dr. Wood takes it for granted that his opponents are those, and those alone, who have in the past disapproved of various matters in connexion with the management of the association. This is not so. I myself have been seldom in agreement with the dissatisfied members, particularly as regards their methods of expressing dissatisfaction, and there are many members who have hitherto been thick and thin supporters of the managers of the association who feel that in the matter under discussion they must reluctantly rank themselves on the other side. The reason is not far to seek. The question at issue is not one of domestic management, but involves a reversal of the fundamental policy of the association. It is a question, moreover, which the general nurse has little difficulty in grasping, since it appeals directly to her sense of self-preservation. It is well known that any woman who pleases to do so can at present wear a uniform and call herself a sick nurse. Indeed, incompletely trained women are competing with fully-trained nurses to an extent which is only realised by those having business in the byways of nursing work. In these circumstances, and when competition was even less acute than at present, the Royal British Nurses' Association was formed as a protection both for the public and the general nurse. The very purpose of its existence would therefore be destroyed by admitting incompletely trained nurses to its register. The principle is bad, and, consequently, it is unnecessary to withhold criticism until "the details have been discussed by the executive committee."

It is necessary to emphasise the fact that arguments in favour of the scheme which deal with the thoroughness of asylum training are immaterial, since such training, however thorough, must be incomplete. Nevertheless, in order to prevent the continued reiteration of the irrelevant argument that the certificate of the Medico-Psychological Association "can only be procured after a rigid curriculum" and "stringent examinations inferior to no examinations for hospital trained nurses, nay, vastly superior to many," I venture to quote the following significant paragraph from a severely impartial article appearing in the current number of

Hosted by Google

the *Hospital*: "After a study of the report of the committee appointed to consider the question (i.e., asylum training), and with some knowledge of the working of an asylum, we are reluctantly forced to believe that while some of the men and women holding these certificates are perfectly well equipped for their work there must be many who have little practical acquaintance with some of the most important and every-day duties of a nurse. In these cases the certificates can have little more value than the St. John's first-aid and nursing certificates."

"Properly trained and qualified mental nurses" would no doubt be benefited by association and registration. Let them, then, organise themselves. Amalgamation with general nurses would be of doubtful value to them as regards their special work, while it would do incalculable harm by destroying the distinctive position at present conferred by the Royal British Nurses' Association on its members. It is true that certain precautions are suggested to prevent confusion, but everyone having a practical knowledge of the disadvantages under which the general nurse already works must be aware that such theoretical distinctions would prove ineffective. What this confusion between incompletely and fully trained nurses means to the medical profession and the public one has only to look round to realise.

I am, Sirs, yours faithfully,

West Ham, Jan. 2nd, 1897. JOHN BIERNACKI.

VACCINATION OFFICERS AND THE PROPOSED AMENDMENT OF THE VACCINATION LAW.

To the Editors of THE LANCET.

SIRS,—I think it may interest a majority of your readers and be of advantage to many who are starting in life to relate the experience of a lifetime in the Poor-law service. After serving as deputy (being in partnership with a Poor-law surgeon in the country) for three years, I was appointed to a newly-formed district, which I worked for nine months, when the office of resident medical officer to the Birmingham Workhouse Infirmary became vacant, to which I was appointed, there being seventy-two candidates. For upwards of eight years I performed all the duties solely, which were satisfactorily done, as proved by the Local Government Blue-book and testimonials received from the board of guardians and Poor-law inspectors. The late Dr. Seaton of the Local Government Board in the year 1868 recommended to the guardians of Birmingham, and the Local Government Board adopted the recommendation, that a specialist for vaccination be appointed for the whole of the parish, devoting all his time to the duties and not to accept any other engagement. I was induced by the representations made to me of the emoluments (which proved fallacious) and the permanency of the appointment if after the first twelve months the duties were satisfactorily performed to undertake the office. I have now for twenty-eight years fulfilled the duties without any other engagements, except being a licensed teacher of vaccination appointed by the Privy Council and a supplier of vaccine to the National Vaccine Establishment, making nearly forty years' consecutive service. I am approaching the time when failure of accuracy of nerve touch and eye-sight may occur, and am now informed that although the vaccination officers who have been appointed to register the certificates issued by me, and paid by fees, are eligible for superannuation as Poor-law officials, I, the medical officer, for some reason am excluded and thus debarred from receiving a retiring pension under the Poor-law Superannuation Act. Therefore, I presume I must continue against conscience to perform duties of very grave responsibility or fail to meet the requirements of a family by being kicked out, all fame as a medical man having been knocked out by the prolonged sitting of the Royal Commission and the prejudice aroused thereby.

I am, Sirs, your obedient servant,

EDMUND ROBINSON, M.D. St. And., M.R.C.S. Eng., L.S.A.

Birmingham, January, 1897.

"ALLEGED ARSENICAL POISONING."

To the Editors of THE LANCET.

SIRS,—I am much indebted to Dr. Stevenson for his courteous reply to my communication and regret that I cannot accept his suggestion that my letter was written under a misapprehension. I carefully guarded myself by saying that I had no personal knowledge of the case and that my remarks were founded solely on the report which appeared in THE LANCET. Dr. Stevenson thinks that my criticisms must fall to the ground, but, on the contrary, they are materially strengthened by his statement that the fabric contained approximately only $\frac{1}{1000}$th of arsenic per square yard. The facts are perfectly simple. A specimen of linette was sent to Mr. Bernard Dyer, who found that it contained $\frac{1}{160}$th of a grain of arsenic in the square foot, or approximately $\frac{1}{20}$th of a grain in the square yard. The same linette was sent to Dr. Stevenson and Mr. W. Thomson, and they found only $\frac{1}{1000}$th of a grain in the square yard. A statement such as this does not require criticism, but it would be all the better for a little explanation. Then we are told that Dr. Stevenson cannot detect less than $\frac{1}{200}$th of a grain of arsenic, but Dr. Luff can very readily detect $\frac{1}{5000}$th of a grain, and finds that even $\frac{1}{10000}$th of a grain produces a distinct stain. Arsenic is by no means a rare drug, and I was under the impression that its recognition, even in the most minute quantities, presented exceptionally few difficulties. Most of us have been in the habit of availing ourselves from time to time of the services of our chemical colleagues in the belief that their methods were capable of a very considerable degree of accuracy. If, however, they can get no nearer a definite result than the difference between $\frac{1}{20}$th of a grain and $\frac{1}{100}$th of a grain, or between $\frac{1}{200}$th of a grain and $\frac{1}{500}$th of a grain, I am afraid that a severe blow will be given to our confidence in the value of expert testimony. This divergence of opinion must be capable of some explanation and cannot present such difficulties as to baffle the acumen of the distinguished authorities whom I have named.

I am, Sirs, yours faithfully,

Welbeck-street, W., Jan. 4th, 1897. WILLIAM MURRELL.

"INGUINAL ORCHECTOMY."

To the Editors of THE LANCET.

SIRS,—I am indebted to the letter of Dr. Zum Busch which appears in your current issue, and to a courteous private letter from Mr. Harold J. Stiles, the translator of Kocher's "Operative Surgery" (Edinburgh, 1895), for the information that the inguinal method of orchectomy is not a new one, but was described by Kocher some years ago. I am thus placed in the unpleasant position of having unwittingly claimed as my own what belongs to another. Professor Kocher describes his incision as follows: "A transverse incision is carried downwards and inwards over the inguinal canal a finger's breadth above and parallel to the inner half of Poupart's ligament." It will be seen that this incision does not differ essentially from the one described in my paper—"An incision of from one inch to one and and a half inches long, and slightly curved with its concavity looking downwards and outwards, is made over the external abdominal ring in the line of the spermatic cord." I trust that my paper will not be valueless if it directs increased attention to the value of Kocher's method. Mr. Stiles informs me that since he began to use it he has had no hesitation is excising tuberculous testicles in children attending his out-patient department, without admitting them to the wards at all.

I am, Sirs, yours faithfully,

Guy's Hospital, S.E., Dec. 30th, 1896. W. S. HANDLEY.

THE ISOLATION OF CASES OF TYPHUS FEVER.

To the Editors of THE LANCET.

SIRS,—Am I justified in sending typhoid fever patients to a hospital where typhus fever cases are treated in the same wards? An immediate answer will confer a favour on

Yours faithfully,

Dec. 30th, 1896. A SUBSCRIBER.

*** The propriety of sending cases of enteric fever into a ward in which typhus fever was also being treated would be regulated by special circumstances. Speaking generally, it is no doubt always wiser to treat typhus fever in a ward by itself if the means for doing so are available. There should, however, be but little risk in placing the patient in a

Hosted by Google

ward with typhus fever cases, provided (1) that the typhus fever cases represented a relatively small proportion of those under treatment; (2) that the ward was not overcrowded—i.e., possessing a minimum allowance of 144 square feet of floor space per bed, together with ample ventilation; and (3) that a reasonable amount of care was exercised over the movements of the patients when convalescent. Experience shows that if the foregoing points be insisted upon there is but small chance of harm resulting.—ED. L.

"THE NEW SYDENHAM SOCIETY'S MEDICAL LEXICON."

To the Editors of THE LANCET.

SIRS,—May I suggest the cause of the delay in bringing out the Lexicon of the New Sydenham Society? Is it because the work is in the hands of a general practitioner who has a very large and tedious practice to conduct?

I am, Sirs, yours faithfully,

Jan. 5th, 1897. M.R.C.S. Eng.

"PRIVATE HOSPITALS *v.* MEDICAL PRACTICE."

To the Editors of THE LANCET.

SIRS,—In your annotation in THE LANCET of Jan. 2nd you write that it is suggested in the prospectus of this institution that "long acquaintance on the one side and intimate technical knowledge on the other are no longer needed to bind together the patient and practitioner, nor, indeed, is any personal bond of value." I challenge you to quote a single sentence, or even a word, in the prospectus suggesting anything of the kind. Massage and electricity undoubtedly "form part," as you write, "of the well-worn armament of medical skill," and, that being so, the greater the necessity that masseurs, masseuses, and electricians should be taught their "technical knowledge" with completeness and thoroughness and by a competent teacher. That, as a rule, they have not been so taught is recognised by all practitioners who have had experience in applying these methods of treatment as well as in prescribing them (*and the two are very different*), and they alone can form an adequate idea how the most explicit directions are frequently misunderstood or carried out incorrectly or imperfectly, and what a comfort it is to know where to obtain experienced and skilled assistance. To provide such assistance and to thoroughly train masseurs and masseuses is the chief object of this institution.

I am, Sirs, yours faithfully,

THE GENERAL DIRECTOR.

The London Galvanic and Massage Hospital,
Praed-street, W., Jan. 2nd, 1897.

*** Clearly this place should not be called a hospital, but a training institution for masseurs.—ED. L.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

V.—MANCHESTER (*continued*).[1]

House-to-House Inspection of Hospital Patients.—The Provident Dispensaries and the Prevention of Hospital Abuse.—Dissatisfaction among General Practitioners.

THE five principal hospitals of Manchester differ from the other hospitals I have visited in so far as they have attempted to establish a wage-limit. It is true that many general practitioners complain bitterly that this principle is very inefficiently applied. Some even go so far as to say that the measures taken do more harm than good, for they only serve to render the abuses that exist less obvious. Nevertheless, whether successful or not, I cannot help thinking that these hospitals deserve some credit for having at least attempted to deal with this question. Naturally the most important among them is the Manchester Royal Infirmary. According to the last statistics published there were in 1895 in all 4518 in-patients, 35,569 out-patients, and 1118 home patients. At the convalescent homes of Monsall and Cheadle there were 4375 patients, making a grand total of 45,580 patients, as compared with 43,458 in the year 1894. Out of this number enquiries were made into the financial circumstances of 15,931 and it was found that 584 were not entitled to claim medical relief from the hospital. These figures are given as a proof "that every effort is made to prevent an abuse of the charity."

On inquiring into the details I found that with regard to accidents the prevention of abuse depended upon the perspicacity of the nurse and the surgeon. If the patient seemed in good circumstances his name was marked with a cross and an application would be made to him for a subscription. If the patient is strong enough when his wound has been dressed to go away, he is, if apparently in good circumstances, told not to return to the hospital, but to see for further advice a private medical man. Thus it is maintained at the hospital that even in the case of accidents abuse can only arise for the first emergency, the first dressing, and that after this first care has been given then the patient is sent away or asked to subscribe. The weakness of this arrangement is obvious, for the surgeon and the nurse are not competent to detect all cases of abuse, and even where the well-to-do patient does subscribe to the hospital this is of no benefit to the medical profession. The precautions are more effective and better organised for dealing with ordinary out-patients. The latter have first to apply at an inquiry office situated close to the entrance of the hospital. Here a clerk notes down the applicant's name, age, social state, whether married or not, the number of his family, the earnings of the whole family, and his individual earnings. If he is an adult and single, but living with his family, then the circumstances of the family must be taken into consideration. After all this has been duly noted down the applicant receives an out-patient's card, which bears a number, and he is directed to the medical or surgical side and receives advice and medicine. Twice a week the list of new patients is forwarded to the Manchester Charity Organisation Society, who send their officers to inquire at the patient's home and verify the statements given as to income, &c. Should these statements prove incorrect the out-patient's card is withdrawn, marked, and sent to the hospital. If the patient, nevertheless, returns to the hospital then he must explain why he has come without a card and why he considers himself entitled to relief though the card has been withdrawn. It is then for the hospital authorities to decide whether they will make an exception in his favour and give him back his card. Should the patient refuse to give up his card to the inspector who calls upon him at his own home, the inspector writes and informs the hospital of the fact, and the medical officer's case-book which corresponds with the number on the patient's card is withdrawn from the shelf. Thus, when the patient comes and presents his card it is found that his book is missing, and this has the same meaning as if he had no card. To gain admission as an out-patient a recommendation from a subscriber is of no use, it secures no extra advantage, and at best it is but a matter of form. In-patients, however, must get a recommendation from a subscriber of at least three guineas. Twenty-five per cent. of the in-patients come from the out-patients' department, 20 per cent. come with recommendations from subscribers, and 55 per cent. are accidents, urgent cases, or re-admissions. With regard to the latter some inquiry is made at the bedside as to their means and circumstances. Then the patient, if not very poor, is asked to contribute towards his maintenance. The contributions given by the patients vary from 2*s.* to two guineas per week. Last year they amounted in all to £880.

Seeing that the work of inspection is entrusted to the Charity Organisation Society it was necessary to inquire into the detail of the operations of this association. At the very onset there arises a complication. This is not merely a Charity Organisation Society, but it is the District Provident and Charity Organisation Society of Manchester and Salford; that is to say, the work of preventing the abuse of charity is combined with the work of organising a huge provident dispensary. The theory originally propounded was at least ingenious and sounded very fair. The sick were to be divided into four categories. Those who possessed absolutely no financial resources were to be referred to the Poor-law

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *continued*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *continued*) Dec. 12th, 1896, Liverpool; and (5) Jan. 2nd, 1897, Manchester.

Hosted by Google

authorities. The second category consisted of very poor persons and were sent to the hospitals. The third category were persons who, though poor, yet were able to pay a penny per week, and they were made to join the provident dispensary. If they were ill and had not joined the provident dispensary they were called upon to pay an entrance fee of five shillings and then only were they entitled to immediate medical attendance. Finally, the fourth category consisted of those who, on inquiry, were considered able to pay for a private medical man. This so-called upwards wage scheme was, however, ultimately abandoned, the excuse given being that it was too complicated. It is now thought that medical interests are sufficiently guaranteed in the Provident Dispensary by the fact that the medical officers are allowed to sit on the Board of Management. This, however, is quite another question.

To return, therefore, to the hospital patients, I found that the Charity Organisation Society do the work of inspection for the five leading hospitals of Manchester. Twice a week they receive a list of all the new patients that have applied at these hospitals and at whose homes it is desired inquiries should be made. These lists comprise annually from 50,000 to 60,000 names. The actual number of cases inspected last year was 55,000. Out of this number 21,549 cases were from the Royal Infirmary. The fact is pointed out that the concentration of the work of inspection into one hand greatly facilitates its execution. No one hospital could afford to keep a sufficiently large staff of inspectors, nor could one or two inspectors ever cover the ground in so large a place as Manchester and Salford. The wonder is how the work can be done by the five inspectors who are actually engaged upon it. Each inspector inspects simultaneously for all the five hospitals, and he only inspects in his own district, where he lives and knows every house. He is well acquainted with the rate of wages in the principal trades, mills, &c. It suffices for him to ascertain where a man works and whether he works full time to know exactly what he earns. As this method of inspection was started some twenty-one years ago the inspectors are wonderfully experienced in their duty and the task is comparatively easy, for it is only necessary to find out what is the patient's income at the time of the visit. This may often be ascertained in a few minutes, whereas if it was a case of financial charitable aid it might require half a day or more, because it would then be a matter of character, of past history, and of future prospects. For the hospitals the wages question alone need be answered.

Concerning the cost of this system of inspection the hospitals are supposed to pay half; and, on the grounds that it is a means of preventing the abuse of charity, the Charity Organisation Society pay the other half. Thus the Royal Infirmary has paid £69 for the investigation of 21,549 cases. This, it seemed to me, was a very inadequate payment; and, under the circumstances, I was not surprised to hear that the inspectors in their turn were also insufficiently paid. The senior inspector receives 30*s*. and the other inspectors 25*s*. a week. When we consider the delicate, difficult work they have to do, the tact and diplomacy they should display, and the possibilities of bribery to which they are exposed, it will be admitted that the salary given is very small. Besides, one visit does not always suffice. A patient may declare that he does not belong to a sick fund or to a trade union or that his union does not give him a sick allowance. In that case the inspector must go to the offices of the trade union or to some likely sick club to verify if this is true. Even the porters who stand at the corners of streets on the look-out for some casual employment have clubs of their own. During the last week of my stay in Manchester the inspectors visited 850 cases, or 141 in each of six days. This makes an average of twenty-eight visits per day per inspector—a wearisome and desponding work to perform. I was not surprised to hear that complaints had been made against these inspectors who it was thought by some persons treated the poor people on whom they called rather roughly. How far this complaint is justifiable or not I had no opportunity of ascertaining, but in any case it is impossible to expect all the virtues for 25*s*. a week.

The next great question is the wage limit itself. This I found to be very low—namely, 12*s*. a week for single men or women, 18*s*. for married couples, and 1*s*. 6*d*. extra for each child. Should the inspector ascertain that the patient's income is above these limits, then he must expostulate and urge that the patient is quite well enough off to pay 1*d*. a week and join the provident dispensary. Thus it will be seen that inspecting for the hospitals resolved itself into canvassing for the provident dispensary. Naturally medical men, especially those who were not attached to the dispensary staff, loudly complained, and the Royal Infirmary has now abolished the system. For this purpose it has raised the wage-limit to 15*s*. for single men or women, 21*s*. for married couples, and 1*s*. 6*d*. for each child. If this income is exceeded the inspector must withdraw the hospital card, but he must not suggest that the patient should join the provident dispensary. The inspector must not distribute circulars concerning his institution to the patients of the infirmary, but he may do so to the patients of all the other hospitals. This is undoubtedly apt to cause confusion. It was thought that the two institutions would work harmoniously together; that the provident dispensary would send to the hospitals cases for which a consultation was needed and keep away from the hospitals many of the trivial cases that encumber the out-patients' department. But in practice the provident dispensaries do not like to admit their failure to treat patients, and very generally send merely chronic and incurable cases. Or else the provident dispensary will recommend a patient to the hospital while he is paying his five shillings entrance fee in slow instalments and then take him under their charge. Sometimes, however, they admit members at once and without entrance fee.

The Royal Infirmary, by accepting as patients those who exceed the wage limit, but who contribute something towards their maintenance, naturally takes away from the Provident Dispensary many persons who otherwise would be members. The provident dispensary on its side, having no wage limit, takes in publicans, tradesmen, and others who could afford to pay a private practitioner. An amusing case was related to me of a woman who was surprised to find that her medical man called to give medical advice to her servant. On inquiry she discovered that he was one of the medical officers to the Provident Dispensary and that her servant was a member. Thereupon the woman in question also joined the Provident Dispensary and thus obtained the advice of her usual medical man, but instead of paying him 5*s*. a visit she paid 1*d*. a week, of which magnificent sum her medical adviser received half! A consulting physician also described to me how he applied at one of the offices of the Provident Dispensary, and though he wore a silk hat and frock coat, and certainly did not look poor, no objection whatsoever was raised and all the indications were given so that he might join. Another consultant told me he frequently received a guinea fee from a publican at Deansgate who at the same time was a member of the Provident Dispensary, where he went when troubled by smaller ailments. The poorer general practitioners complain bitterly that their private patients receive leaflets from the Provident Dispensary showing how much cheaper it would be to join and be attended by perhaps better-known medical men. In the face of these assertions it seemed to me a strange anomaly to find that, though the Provident Dispensary is accused of committing many abuses, this organisation should have been entrusted with the mission of preventing the abuse of hospitals. Many of the new medical men in Manchester commenced practice under the auspices of the Provident Dispensary; their object being to gain popularity and to lay the foundations of a private practice they were not likely to prevent abuses. It was in their interest to increase the number of members on their list, and thus abuses inevitably arose The hospitals, instead of going to this institution to help in the prevention of abuses, would act more consistently if they constituted a central hospital board and employed their own inspectors.

It has been suggested that in the same way there should be but one subscription list, and that instead of each hospital incurring very great expense in collecting money one single staff under a central board would suffice for all the hospitals. This, it is true, would destroy the special spirit that animates the patrons and subscribers of each hospital—the sort of fatherly interest they take in their favourite hospital—and thus perhaps lower the sum total of the subscriptions. Doubtless there is much truth in this objection; but whatever may be said with regard to the collection of subscriptions it is only by collective action that a method of inspection can be efficaciously and economically carried out. As it is, even with the 50,000 to 60,000 visits paid per annum by inspectors organised from one common centre there is a large class of patients who altogether escape control. The inspectors cannot possibly go beyond the limits of the

Hosted by Google

boroughs of Manchester and Salford. If a patient comes from beyond the hospitals must trust to his statements. Some years ago an inspector was appointed to investigate these country cases, but the distances were enormous and the cost of travelling so great that it was impossible to visit a fair proportion of the cases. Then the hospital authorities wrote to the clergy, the registrar, and the relieving officers of these distant rural and urban districts to inquire concerning the financial position of patients who had come from their neighbourhood; but, as a rule, no answer was sent. This is all the more awkward as Manchester is the centre of the largest working population of the United Kingdom, and from all the surrounding manufacturing centres and towns patients come pouring in upon the Manchester special and general hospitals. It is always so easy to get a train to Manchester. On the other hand, the very fact that patients come from such distances as, for instance, Rochdale, Bolton, Derby, Windermere, &c., proves that they are not very poor. The railway fare often costs much more than the local practitioner's fee. At the Royal Infirmary, when the clerk, on questioning these patients who come from a distance, finds that they are not poor he makes them pay a 6*d*. or 1*s*. fee before allowing them to obtain advice. This, again, is very good for the hospital, but it is of no help to the medical profession. A patient who could pay a medical man is thus lost so far as the economic interests of the profession are concerned.

Such facts show how widespread an organisation is needed so that an effective control can be established. Not only is it necessary to have a perfect system of inspection within the town, but there should be some established authority in all outlying districts to whom application could be made by town hospitals for information concerning patients that come from these distant districts. Nothing of the sort exists at present and it could only be established by some very powerful organisation, such as a federation of hospital boards or a medical union which counted in its ranks the immense majority of the members of the medical profession. This end is far from attained at present; yet it must be acknowledged that the medical men of Manchester have made several notable efforts to organise the profession. Apart from the local branch of the British Medical Association special bodies have been constituted, such as the Medico-Ethical Association and the Medical Guild. Even the medical men employed by the provident dispensaries have formed themselves into an association which of late has shown signs of awakening. The Provident Dispensary has ten district dispensaries or branch establishments, more than 20,000 members, and employs thirty medical officers. One of these medical officers, Mr. G. H. Broadbent, has been most active in the denunciation of abuses. In the Ethical Section at the annual meeting of the British Medical Association, held at Carlisle (1896), Mr. Broadbent read a paper on the Manchester Provident Dispensaries, which he accused of sweating profits and creating a reserve fund of £1450 out of the labour of its medical officers. The dispensary also sapped the practice of general practitioners to the extent of thousands of pounds by accepting as members people who could well afford to pay ordinary medical fees. Mr. Broadbent related that two years after this provident dispensary had first been established on the upward wage system, which I have already explained, about seventeen medical men had joined. They soon found, however, that unsuitable persons were allowed to become members, so the medical officers decided to resign in a body. The Provident Dispensary thereupon imported two new medical officers and gave them a guarantee for a fixed income. With good management and the aid of these two medical officers the dispensary proved a success, grew, and has now branch establishments. Mr. Broadbent adds: "These provident dispensaries have not picked up those they were intended for. And why? Is it not likely that that mighty man, the collector, will prefer to go for his money to people who always have it ready, to houses that are clean rather than to those which are dirty, where payments are not made regularly? And will it not be more agreeable to the medical men to go to clean, respectable houses, even if they are robbing their fellow practitioners of their legitimate patients? Cases have been known where medical officers have paid the collector a commission for increasing the number of cases on their list."

Nevertheless, and as already remarked, the medical men in the service of this dispensary are awakening, for in the course of the year 1895 the Manchester and Salford Provident Dispensaries and Medical Officers' Association met and unanimously passed the following resolution:—

"That this meeting of the Association of the Medical Officers to the Manchester and Salford Provident Dispensaries protests in the most earnest manner against the methods of propagating the provident dispensary system by advertising and canvassing practised by some of the committees of the branch. Such methods are directly opposed to the ethics of the medical profession and are not calculated to promote the real welfare of the dispensaries, and if persisted in will make it impossible for any self-respecting medical officer to retain his connexion."

In the face of this resolution and of these denunciations I cannot but repeat that it does seem strange that the hospitals of Manchester should have called upon this very institution to help them to check abuses. Yet such is the fact, and it is fully set forth in the "Twenty-first Annual Report of the Manchester and Salford Provident Dispensaries Association" (1895). On page 12 this report states:—

"The payments from subscriptions, sick fees, and entrance fees of the members of the several dispensaries amounted during the year to £4422 9*s*. 9*d*., and the sum paid to the medical staff was £2612 15*s*. 11*d*., as compared with payments of £4383 17*s*. 10*d*. in 1894, when £2600 15*s*. 6*d*. was paid to the medical staff."

Then on the very next page appears the following statement:—

"The officers of the District Provident Society report that the investigations conducted by them into the circumstances of the applicants for charitable medical relief at the various hospitals in connexion with the association have been continued during the past year, the number of cases received for investigation being slightly in excess of those for 1894. The percentage of those found to be entitled to gratuitous medical treatment was 93·84, being out of the total number visited 2·02 less than in 1894. At the Royal Infirmary the percentages of those who were found to be able to subscribe to a provident dispensary have been as follows:—1891, 9 per cent.; 1892, 6 per cent.; 1893 5 per cent.; 1894, 3 per cent.; 1895, 4 per cent. At the Clinical Hospital the percentages have been as follows:—1891, 7 per cent.; 1892, 6 per cent.; 1893, 4 per cent.; 1894, 3 per cent.; 1895, 6 per cent. At the Children's Hospital the percentages have been as follows:—1891, 9 per cent.; 1892, 7 per cent.; 1893, 8 per cent.; 1894, 7 per cent.; 1895, 9 per cent. At the Ancoats Hospital the percentages have been as follows:—1891, 4 per cent.; 1892 and 1893, 3 per cent.; 1894, 2 per cent.; 1895, 6 per cent."

Finally, the report concludes by giving a table which shows "the percentages from year to year of those applicants to the medical charities coöperating with this association who were found, on investigation, to be ineligible for gratuitous medical relief, and who were in consequence referred to the Branch Provident Dispensaries." It was in 1875 that the system of inspection was first applied and then the proportion of ineligible cases found was truly startling, for it amounted to 42·32 per cent. of the applicants. The inspectors must have acted as a wholesome scare to the people who too freely availed themselves of medical charities, as the next year the proportion exceeding the wage limit fell to 24·50. In 1879 it further fell to 13·61 per cent. The following year the proportion rose to 14·76. Then, with some fluctuations, the percentage fell to 9·29 per cent. in 1887. After that it was always below 7 per cent., and this has continued up to the present time, excepting, however, the year 1891, when the proportion amounted to 7·49 per cent. From these figures it would appear that a very great reduction of unsuitable cases has been effected, but I found that many general practitioners challenged these figures. They pointed out that originally the wage limit was 10*s*.; then it was raised to 12*s*., and finally to 15*s*. What would be considered a proper case to-day was an improper case a few years ago. Also, the inquiry was declared to be perfunctory and of no real value. "It did more harm than good," exclaimed one general practitioner, for it conveyed the impression that precautions were employed. It was not possible that there should be so many persons in the town in receipt of such small wages. The inquiry was only a test of the patient's memory. The patient had only to repeat to the inspector the same details which he had given to the clerk of the hospital. If the applicant was able to tell the same lie twice running he secured admission as a hospital patient. Only recently one of his patients, a woman in receipt of an income of £50 a year and whose husband was earning 15*s*. a week, had been admitted into the infirmary. A warehouseman earning more than 21*s*. a week and a maidservant in the employ of a wealthy family had been quite recently accepted at the infirmary. A child had just concluded a month's treatment as an in-patient at the Children's Hospital, though her parents pay £22 a year rent and had re-furnished their house throughout at the very moment their child was in hospital. Such were some of the cases mentioned to me by different general practitioners so that I might realise that abuses still existed in spite of the inspections; they also objected to the inspectors because instead of telling the applicants who had means to call in

Hosted by Google

a general practitioner they advised them to join the Provident Dispensary. Finally, it was suggested that the proper thing would be to hold, if it were only for one day, an independent inquiry. In spite of these criticisms I cannot but think that the authorities of the Manchester hospitals have done more to prevent abuses than those of any other town I have yet visited, nevertheless it will be seen how far from perfect are the methods they have employed. Abuses undoubtedly still exist and dissatisfaction is keenly prevalent.

(To be continued.)

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Death of Alderman Clay.

ON the 14th of last month, at the special meeting of the trustees of the Manchester Royal Infirmary, Alderman Clay attacked the scheme for the rebuilding of the Royal Infirmary from the Corporation point of view with a vigour and warmth that testified to his own convictions on the matter. On the 16th he "caught a chill," pneumonia developed, and he died on the 24th ult. at the comparatively early age of fifty-six years. He was a man of great energy, much of which was devoted to municipal work. As chairman of the Improvement and Building Committee he did good service, indirectly at all events, in aid of sanitation, not more, perhaps, in the clearing and opening out of old thoroughfares and dealing with the lines of new streets than in seeing to the carrying-out of the "building by-laws," which, though cavilled at by a few, place salutary obstacles in the way of the jerry-builder. He looked at the infirmary question too exclusively from the corporation standpoint, the preservation for the city of an open space, while somewhat unmindful of the fact that it was the duty of the trustees to make the best of the property for the benefit of the patients. The alternative schemes propounded after the meeting showed, however, that he did not oppose simply for opposition's sake or from hostility to the infirmary board, but that he thought another solution of the question would be best in the interests of all. He was a power in the city council, and the large attendance at his funeral of men of all views, creeds, and parties showed how much he was respected and regretted.

"Home made Whisky."

At Darwen last week an ingenious hawker was charged with hawking and selling methylated spirits. He appeared to have been carrying on the business for more than four years. "In his rooms a quart bottle containing methylated spirits was found and also a kind of filter made of charcoal and brown paper, through which spirit diluted with water was passing. The effect was that the nauseous smell was removed." Some spirit already treated was also found. The prisoner said he had got the idea from a paper and "had carried on the business since he had lost his eyesight." His customers were chiefly women. One woman said she bought a pint of this whisky, as the prisoner called it. He told her it was for outward application, and was "good for rheumatism," but she and three other women drank it. Another said she had bought a pint of "home-made whisky" every week for the past six months. "And you are still alive?" asked the clerk. "We used to rub with it and sometimes we drank it." Another woman who had bought eight or nine pints of it had now ceased to do so "because it had made her ill." He told one man to whom he sold it that "the spirits were good for sciatica," from which he was suffering. He did not sin from want of knowledge, for he had been convicted of a similar offence at Bolton in 1893. "He now pleaded guilty, and was fined £25 and costs in each of two cases for selling and £1 and costs in two other cases for exposing the spirits. In default of payment he would be imprisoned for six months." It is not stated as to whether or not his profits enabled him to pay the fines.

Manchester Literary and Philosophical Society.

The above society is said to be the oldest, and is assuredly one of the most distinguished, of its kind. In its early days its title was appropriate and characteristic of its objects, but it is questionable whether it can claim to be so now. And, indeed, we may go back to the names of Joule and Dalton as indicating the fact that physical science has brought it more renown than literature and philosophy, while now more than ever is it given up to applied science. Manchester has grown into a huge city, and most of those who care to do so live beyond its confines. The character of its membership, therefore, has altered with the times. There are fewer literary and scientific amateurs, according to a document dealing with its own archives recently issued by the society, and "while the number of members professionally engaged in scientific pursuits, either as investigators or teachers, has increased, there is a considerably smaller number engaged in business who either possess a taste for scientific knowledge themselves or are desirous of encouraging others in its pursuit." This statement ignores literature and philosophy and everything but "science," and doubtless, as the *Manchester Guardian* says, "the present council would be rather surprised by the offer of papers on the Pleasures Arising from a Survey of Nature, on the Application of Natural History to Poetry, or even by those delightful illustrations of Sterne which were supplied by that keen critic, Dr. Ferriar." These changes are, no doubt, inevitable. Science is well represented, but literature and art have sought other abodes, while no one seems to know whither philosophy has fled.

Merchants and Adulterated Butter.

A firm of butter merchants was summoned the other day at the county police-court for "giving a false warranty relating to certain Irish butter," the prosecution being arrived at by "retrograde progression." First of all a retail dealer was summoned for selling butter containing an excess of water. He put in a warranty given by the defendant firm and the case was dismissed. The butter on analysis was found to contain 21·08 of added water. For the defence it was pleaded on behalf of the firm that the butter was purchased as pure, and unless every cask of butter sent to them was analysed it was quite impossible to discover if there had been adulteration. There is always some water in butter, and those engaged in the trade say that if there were none it would not be good, but it is difficult to arrive at what they consider the correct amount. The magistrate said it was clear that the butter contained 21·08 parts of water as stated, "whereas it should not have contained more than 17 or 18 per cent." He did not believe that the Manchester trade added water to the butter, but sold it as they received it. So the fraud, if it is a fraud, is put back a stage further to the farmer or the butter-factory. Mr. Yates imposed the minimum penalty of twenty shillings and costs.

Jan. 5th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Cardiff.

THE Cardiff Health Committee have been taking into consideration the necessity for increased accommodation at the sanatorium and the borough engineer has prepared plans and estimates for a new wing which will cost approximately £20,000. It is proposed to provide for two additional male wards and one paying patient's ward. A porter's lodge is also included, although some of the members considered this unnecessary. There have recently been three interruptions in the supply of the electric light at Cardiff. The first occurred on Nov. 27th owing to a mistake made by an engine-driver, but this was rectified in three minutes. The second was on Dec. 4th and was caused by a transformer burning up. The last occurrence was on Dec. 12th, when about 4 P.M. owing to a fire at the switchboard the electric light failed throughout the districts of Cardiff. In about a quarter of an hour the greater portion of the private consumers were supplied, but it was 11 P.M. before the remainder were provided.

Erith House Home for Invalid Ladies, Torquay.

At the forty-second annual meeting, held at Torquay on Dec. 18th, the annual report showed a deficit of £178 on the past year as against a profit of £27 on the previous year. The number of ladies visiting the home has of late years steadily decreased; during the past season only twenty ladies availed themselves of its privileges, as against thirty in the previous year. The chairman said that it would be necessary to seriously consider whether the home should be carried on. It was mentioned that the institution had been advertised in various papers, but that not a single lady had been admitted as the result. Dr. Hamilton Ramsay acknowledged a vote of

Hosted by Google

thanks to the medical officer, and said that in spite of things looking dark he hoped they would avoid closing the institution. Erith House Home is doing an excellent work, and doubtless if its advantages were more widely known it would be more liberally supported.

Death of Mr. H. R. Hudson of Newport, Mon.

Mr. Henry Rochfort Hudson, L.R.C.P., L.R.C.S. Irel., of Newport, died in Ireland on Dec. 16th. Mr. Hudson was much esteemed in Newport, where he had been for over twenty years. He was public vaccinator for the Newport and St. Woolas District of the Newport Union and surgeon to several clubs. Mr. Hudson was a native of Arklow, county Wicklow; he had been in failing health for the past year, and last summer he became worse and went to Ireland. He was forty-eight years of age at the time of his death, and leaves a widow and six children, for whom great sympathy is felt.

Death of Mr. Thomas Browne Anstie, J.P., M.R.C.S. Eng., L.S.A.

Much regret is felt in Devizes at the death of Mr. T. B. Anstie, J.P., M.R.C.S. Eng., L.S.A., which occurred on Jan. 3rd. Mr. Anstie was one of the oldest inhabitants of the town and had been in practice in Devizes for over half a century, when he retired. He was a magistrate for the borough and honorary consulting surgeon to the Devizes Cottage Hospital. Mr. Anstie was educated at St. Thomas's Hospital and took the qualification of M.R.C.S. Eng. in 1841 and the L.S.A. in the following year.

Jan. 4th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh Royal Infirmary.

THE annual meeting of the subscribers to the Edinburgh Royal Infirmary was held on Monday last, the Lord Provost presiding. The annual report showed that the total number of in-patients treated during the year was 9478. Of these there were dismissed cured 3945, relieved 3482, and on other grounds 807. There died in the hospital 596. The medical and surgical cases were about equal in number. The average daily number of patients in hospital was 707, and the average time under treatment for each patient was 27·3 days. The number of deaths within forty-eight hours after admission was 150. In the out-patient department 28,110 patients had been attended to. The total ordinary receipts amounted to £30,682, which was a decrease of £403 compared with the previous year. Contributions and legacies under £100 amounted to £17,515. Regret was expressed that there had been a falling off in church collections, while contributions from employés in public works had increased. On fees from students there was a falling off of £180. The ordinary expenditure amounted to £39,282, being a decrease of £113 on that of the preceding year. The cost of maintenance was 1*s.* 6½*d.* more, and the medical expenditure 2*s.* 2¼*d.* less, per occupied bed. The cost for the year of each occupied bed was £55 11*s.* 2¾*d.*, which is 3*s.* 0¾*d.* above last year's rate. This rise was attributed to a higher contract price for butchers' meat and bread. The Lord Provost, in speaking to the report, pointed out the increase in the number of out-patients, and suggested that persons went to the infirmary for advice who ought to go to their private medical attendants. Dr. Batty Tuke raised the question of the site of the proposed new laundry and objected to its being built in Lauriston-lane. He also drew attention to the out-patient department and dwelt upon the need of increased accommodation. Miss Louisa Stevenson also spoke of the discomfort to which out-patients were exposed and held that it was of the utmost importance that a new out-patient department should be established. This led to considerable discussion and the matter was remitted to the committee of contributors. Five managers were re-elected and a second lady was also added to the board in the person of Mrs. Marcus Dodds, wife of an eminent theological professor in the Free Church College.

Annual Report of the University of Edinburgh.

During the past year the total number of matriculated students, including 188 women, was 2825. In the Faculty of Medicine there were 1421 students; of these 616 belonged to Scotland, 431 were from England and Wales, 91 from Ireland, 55 from India, 202 from British colonies, and 26 from foreign countries. The number of women attending extra-academical lectures with a view to graduation in medicine at the University was 68. The McEwan University Hall is likely to be completed and inaugurated during the coming spring. Reference is made in the report to various incidents in the history of the University during the past year, all of which have already been noticed in THE LANCET from time to time and need not now be repeated.

Dairy Prosecution in Dumfries.

An important decision in a dairy prosecution case was given in Dumfries last week. The charge was against a dairy farmer for employing in his dairy a woman who was "suffering from a dangerous infectious disorder—namely, infectious tonsillitis," and also three other women to milk, in whose families there were cases of a similar nature. The action was taken by the local sanitary authority presumably on the recommendation of their medical officer of health who was a leading witness in the case for the prosecution. Several local medical men and others appeared for the defence who seem to have taken up the position that the persons referred to were not suffering from an infectious disorder. The medical officer for Midlothian gave it as his opinion that tonsillitis, except where it existed as a symptom of scarlet fever, diphtheria, or typhoid fever, was not infectious. The sheriff dismissed the complaint and found the local authority liable in expenses.

Re-opening of Medical Classes in Edinburgh.

Most of the medical classes re-opened on Tuesday after the Christmas vacation, but it is needless to say that all the students have not yet returned to work.

University of Glasgow.

A statement showing the number of students in every one of the University faculties has just been published, together with the numbers of the previous seven years. It appears that, whereas in 1889 the number of students was 2101, in 1896 it had fallen to 1602, a diminution of 499. This decrease has been mainly amongst the arts students, the numbers in this faculty in 1889 being 996 and in 1896 571, and is, no doubt, due to the increased severity of the entrance examination and to the more severe conditions demanded of the student who desires his class attendance to count towards graduation. In medicine the numbers have fallen from 818 to 621; this is, in part, however, only an apparent decrease, as in 1889 students attending chemistry, natural history, and other medical classes, with a view to graduate in science, were counted in the faculty of medicine, whereas now they are placed in the newly-formed faculty of science. In so far as the decrease is real it appears to be due to the institution of the five years' curriculum and the increased stringency of the preliminary examination. It is generally allowed that this examination has been in certain respects too severe, and the student has now the option of taking it in two sections instead of being compelled to pass in all the subjects at a single sitting. The above figures do not include women students of whom during the present session there are 245.

Glasgow Maternity Hospital.

Mr. John Edgar, M.A., B Sc, M.B. Glasg., Professor of Midwifery in Anderson's College Medical School, has been appointed assistant physician to the hospital, in succession to Mr. R. Jardine, M.D. Edin., promoted to be physician.

Glasgow Eastern Medical Society.

At a recent meeting of the society Professor Gairdner paid an eloquent tribute to the memory of the late Dr. Mather, first president of the society, speaking of him as a sound, honest, and honourable practitioner, careful of every rule of medical honour, and a man of fine instincts and sympathies.

Christmas at the Glasgow Infirmaries.

The annual meeting of the nurses was held on Dec. 26th, when an address was delivered by Mr. Jas. Boyd, vice-chairman of the board of management, and a musical programme, under the direction of Mr. Allan Macbeth, Principal of the Athenæum College of Music, was submitted. Afterwards the gifts for the patients from the annual Christmas tree were distributed and the visitors had an opportunity of seeing the wards, which for the most part were brightly decorated. At the Royal Infirmary there was, as usual, a meeting on New Year's Day, addresses being delivered to the nurses by the Lord Provost and others. Dr. Peace, organist

Hosted by Google

to the cathedral, together with members of his choir, gave a number of musical selections.

Glasgow Hospital Reports.

It is understood that a movement has been inaugurated with a view to collect and publish in an annual volume the most important results of clinical and pathological work at the various Glasgow hospitals. There is a general feeling in favour of the movement, and the promoters have received promises of sympathy and support from the leading physicians and surgeons. It is probable that an official statement will shortly be issued.

Aberdeen Royal Hospital for Sick Children.

The expenditure last year amounted to £2633 9*s.* 5½*d.*, 653 patients having been treated at an average daily cost of 2*s.* 3*d.* The new buildings for the accommodation of nurses (29) and servants (9) are expected to cost £3000, and the directors appeal to the generosity of the public of Aberdeen and districts for subscriptions, of which £1050 from six donors have already been intimated.

Hospital Sunday in Aberdeen.

On Sunday (Jan. 3rd) the church collections in Aberdeen for the benefit of Aberdeen Royal Infirmary amounted in the aggregate to £932 10*s.* 9*d.*, but several congregations have yet to send in a return.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Main Drainage of Dublin.

A REALLY serious effort to improve the sanitary condition of the city and to lower its death-rate is now being made by the Dublin Corporation. The main drainage works were commenced on Aug. 24th last. After prolonged delay caused by a building strike the first two contracts were undertaken by Messrs. H. and J. Martin. These cover the construction of the sewers and auxiliary works for intercepting the sewage from the river Liffey and from the smaller streams, the Toltga, Camac, and Poddle. Six gangs of men are now at work, four of these on the north quays, one at St. Michael's Hill, and one near the Kingsbridge Station. The works at present cover in the aggregate about a mile of ground, the average number of men employed being between 300 and 350. The cuttings along the quays are necessarily very deep, and many difficulties have already been encountered owing to leakage of water from the Liffey alongside. Every precaution to prevent serious interference with traffic is being taken, and at various positions, such as the southern end of Sackville-street, the sewers are being constructed in tunnels.

The Trial of the Maguires for Murder.

Two long and also strong letters have recently appeared in the Dublin daily papers in connexion with this case—one from the solicitor to the prisoners and the other from Dr. Thompson of Omagh, one of the witnesses for the defence. Mr. F. J. O'Connor reminds the public that there were two trials in which he acted for the prisoners, one at Omagh in July, and the other recently in Belfast. He then goes on to complain strongly of the expressions used at the latter trial by the Attorney-General in his opening address, in which he attributed vanity, pretension, and ignorance to the medical men—namely, Dr. Thompson of Omagh, Dr. Henry Bewley of Dublin, and Dr. Lorraine Smith of Belfast. Dr. Thompson in his letter bitterly resents the observation by the judge, Sir Peter O'Brien, to the jury that "he hoped that he (Dr. Thompson) was an honourable man and that he would be successful with his patients in the district to which he belonged." This remark seems certainly to have been, to say the least of it, uncalled for and, moreover, proved that the learned judge was not at all familiar with the north of Ireland, where Dr. Thompson has been for many years very well known and very highly esteemed.

The Funeral of the late Sir George Owens.

The funeral of the late Sir George Owens, M.D., J.P., which took place on Saturday morning, was very largely attended and testified to the high esteem in which the deceased was held by the citizens of Dublin as well as by the members of his own profession. The Lord Major, the high sheriff, Lord Ardilaun, Sir William Kaye, C.B., Sir Andrew Read, Sir Robert Forster, the Solicitor-General, the Dean of the Chapel Royal, Sir Frederick Falkiner, Sir Francis Brady, Sir William Porter, Bart., Sir Robert Sexton, D.L., &c., &c., were present, while among medical men there were the Presidents of the Royal Colleges of Physicians and Surgeons and the best-known members of the profession in Dublin.

The Sanitary State of Belfast.

At the Belfast police courts on Dec. 29th, the owner of property in Hopp's-court was summoned by the Belfast Corporation for having premises in a state injurious to health and unfit for habitation, and the magistrates made an order closing them. It is stated that there will be an appeal.

The New Infirmary for Omagh.

At a meeting of the executive committee, held on Dec. 30th (the Duke of Abercorn in the chair), it was reported that the contractor refused to take the contract on the original terms, whereupon it was decided to increase the contract by £234, which would raise it to a total of £8000, added to which the architect's fees and heating would bring the total cost of the Infirmary to £10,000. This would leave a deficit of £4000, which it is hoped that subscribers in the county of Tyrone will make up.

The Notification of Infectious Diseases.

The city corporation of Belfast at their first meeting this year adopted the Notification of Infectious Diseases Act, 1889, by 18 to 8 votes. At the same meeting it was announced that the annual death-rate, calculated on a population of 300,000, was 22 5 per 1000, the lowest for many years past. In the previous year it was 24·8, calculated on the same population. In his address, reviewing the events of the previous year, the Lord Mayor spoke of the desirability of granting a portion of the site of the present District Lunatic Asylum as a site for a general hospital, and he thought that the corporation might make a grant out of the gas profits under Section 59 of the Act of 1874, which says: "In any year in which the average price charged for gas shall not exceed 3*s.* 9*d.* per 1000 feet the surplus profits from the manufacture of gas may be applied by the corporation to public purposes." He thought there could be no more beneficent purpose to which to apply them.

Progress and Prosperity of Belfast.

Belfast has made great advances in the past year. The number of buildings for which plans were approved was 3118, as against 3011 in 1895; the number of streets constructed was eighty-five, as compared with forty-three in the previous year; and the valuation of the city has increased by over £53,000. The great shipping firm of Harland and Wolff, of which the Lord Mayor is a partner, has launched the largest amount of tonnage that has ever been produced by one firm in a year, the record including the largest vessel afloat. The five great Government dockyards of England have only produced 71,000 tons, against 81,000 tons by Harland and Wolff.

Untrained Midwives.

At an inquest held in Belfast on Dec. 21st in reference to the death of an infant a woman was examined who said that she was a housekeeper and practised as a midwife. She could read, but could not write. She attended as a midwife at the birth of the child whose death was under consideration. The child was born in a dying condition, but she did not send for a medical man, and she did not advise that one should be sent for. She could not say what was the matter with the child; at birth the infant simply gasped. She did not understand the term "artificial respiration." Dr. S. Alexander, dispensary medical man of the district in which the child died, said the father of the child and the midwife came to register the infant's death with him, and as they had no certificate he refused. Subsequently the father brought him a letter from a medical man stating that he saw the child seven hours after death and that he believed death was due to natural causes as far as he could judge from a superficial examination of the body. He (Dr. Alexander) then gave information to the police. Dr. Alexander said a large number of so-called midwives practised in Ireland without qualifications of any kind. He had reason to believe that many children who were buried as stillborn had been born alive and owing to want of proper treatment they had died and were registered as stillborn. He thought the best remedy would be to have all women

Hosted by Google

practising midwifery registered under a proper certificate. He thought the child died from asphyxia. It might have lived if medical attention had been procured. The coroner commented strongly on the fact that Belfast was overrun with a class of persons calling themselves midwives who were ignorant of the very rudiments of midwifery which they presumed to practise, and he illustrated this by the circumstance that the midwife examined in this case did not know the meaning of the word "respiration," and when he (the coroner) explained what restoring respiration artificially was she replied, "What did she know about children's ailments?" He also referred to the non-registration of stillborn children, which he thought was a serious matter. The jury found that the infant died from asphyxia, and that if medical attendance had been provided the child's life in all probability would have been saved, that the neglect on the woman's part was not criminal, and that the coroner be requested to bring the midwifery subject before the Belfast Dispensary Committee and to take such steps in the matter as he (the coroner) might consider necessary.

(FROM OUR OWN CORRESPONDENT.)

A Rare Complication of Whooping-cough.

PROFESSOR BERNHARDT reports in the *Deutsche Medicinische Wochenschrift* a case where whooping-cough was complicated by spinal symptoms. A girl aged five years, who had been suffering from whooping-cough for about ten days, was after a severe paroxysm suddenly seized with tonic rigidity of the lower extremities so that walking or even standing became impossible. The power of speech and the functions of the sensory nerves continued normal. The tendon reflexes were increased and the adductor muscles of both thighs were strongly contracted. Neither fever nor cerebral symptoms were present. In the course of several weeks the child's state gradually improved so that after two months she could move her legs and flex her knee-joints fairly well, but the spasms of the muscles and the exaggeration of the reflexes continued. After four months the power of walking was regained. A year after the first illness the child was attacked with double parotitis and the spinal symptoms once more appeared, so that she could only walk with difficulty and by a succession of spasmodic movements; slight urinary troubles also developed themselves. A course of baths at the Oeynhausen springs proved beneficial, and when Professor Bernhardt saw the child some weeks ago she was able to walk, run, and jump, but the reflexes were abnormally strong and micturition was more frequent than natural. No atrophy of the muscles or other symptoms of degeneration were present. Professor Bernhardt points out that the case is probably to be classified as spastic spinal paralysis owing to myelitis caused by the specific virus of whooping-cough. He does not consider that there was hæmorrhage into the medulla because the muscular paralysis which is characteristic of this affection did not follow the spastic symptoms. He is also opposed to the view that the case might be a severe manifestation of hysteria, because the child shows no other hysterical indications whatever. Cerebral troubles complicating whooping-cough have been sometimes described, but affections of the spinal cord and the peripheral nerves are extremely rare in this disease. Möbius published two similar cases in 1889; the first occurred in a boy of three years of age who after whooping-cough suffered from a paresis of the arms, the legs, the cervical muscles, and the diaphragm. The tendon reflexes were diminished, but sensation and the functions of the brain and the intestines were normal. The lesion was evidently slight, no atrophy ensued, and all the symptoms soon disappeared; it is not improbable that the case was only one of peripheral neuritis. In the second instance a girl aged two and a half years on the sixth day of whooping-cough was seized with paresis of the legs, loss of the tendon reflexes, and incipient degeneration of the peroneal muscles. The nervous affection began with high fever, the paresis of the legs did not entirely disappear, and the case proved to be one of myelitis. It is evident, therefore, that whooping-cough is practically free from any tendency to originate affections of the spinal cord and the peripheral nerves.

The Toxins of Diphtheria and Tetanus.

Professor Brieger and Professor Boer announce in the *Deutsche Medicinische Wochenschrift* that they have succeeded in separating the toxins of diphtheria and tetanus in an amorphous form. It is easy to precipitate these toxins from their solutions by means of zinc salts, but the further treatment of the compounds formed in this way presents some difficulties, for many of the usual chemical re-agents have a destructive effect on the toxins. It would be too long to describe all the details of the rather complicated procedure, but it may be mentioned that in the preparation of the toxin the bacilli must be cultivated in a medium containing no albumin; human urine was the fluid selected. The specific toxin of diphtheria is described by the investigators as not giving the re-actions of an albumin or a peptone; it must, therefore, not be classified as an albuminous substance. Alcohol, ether, acetone, and acids destroy it, but weak alkalies do not affect it. Oxidising substances, such as potassium permanganate, also destroy the toxin, but reducing substances have no injurious influence on it even after twenty-four hours' contact. The indifference of the toxin to substances which have a reducing effect is very important, for according to the researches of Ehrlich such substances are continually produced in the organism. It appears, moreover, that the pathogenic action of the bacilli is quite different from that of the toxin. Subcutaneous injections of the bacilli produce an intense necrosis at the place of injection without the internal organs undergoing the alterations characteristic of diphtheria. It was already known that diphtheria bacilli produce local necrosis, but it is now pointed out for the first time that this necrosis depends, not on the toxins elaborated by the bacilli, but on the actual bacilli themselves.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Bacillus of Yellow Fever.

THE Roman Accademia di Medicina is now in possession of the monograph in which Professor Giuseppe Sanarelli, a distinguished *alumnus* of the University of Siena, founder and director of the Istituto d'Igiene Sperimentale at Montevideo, claims to have discovered the infective microbe or bacillus of yellow fever. The discovery will ere long be made *publici juris;* meanwhile, a word or two as to Dr. Sanarelli himself will not be without interest. Last year, when the first cases of the fever in an epidemic form were reported in Brazil Dr. Sanarelli repaired to the lazaretto on the island of Fleres and subjected to minute post-mortem examination every accessible victim to the disease. Having, by numerous preparations, provided himself with the *matériel* for his preliminary studies, he next proceeded to Rio Janeiro and took up his abode in the very midst of the infected locality—in a part of the city, in fact, where yellow fever is endemic. There he continued at work for two months, prosecuting his researches minutely and steadily, till he himself was struck down by the malady, remaining for a week in much danger. He recovered, however, by treatment of his own devising, and returned to his post at the Istituto d'Igiene Sperimentale at Montevideo greatly enriched in *matériel* and experience for the work he had undertaken. His year's work has resulted in the monograph above referred to, and he is now understood to be employed in supplementary investigations, the detailed account of which will, he believes, enable the profession to check his conclusions and, it is hoped, to confirm them.

The Bressa Prizes.

In terms of the will of Dr. Cesare Alessandro Bressa the Reale Accademia delle Scienze of Turin offered a prize for the best scientific work achieved by an Italian savant or inventor during the quadrennium 1893-96. The competition closed on the 31st ult. and the name of the successful competitor will in due course be announced. Another prize, under the same auspices (value 10,000 lire—that is, less income-tax, 9600 lire, or £384), offered to competitors of all nationalities (Italian members of Turin Academy being alone excluded) will be closed to competition on Dec. 31st, 1898. It will be awarded "to any savant of any nation who during the quadrennium 1895-98, in the judgement of the Academy of

Hosted by Google

Sciences of Turin, shall have made the most important or the most useful discovery, or produced the most distinguished work, in physical and experimental science, or in natural history, or in mathematics pure and applied, or in chemistry, or in pathology, or in physiology, not excluding geology, history, geography, or statistics." Intending competitors, I may add, will have to send in their names and work within the term indicated, accompanied by a letter addressed to the President of the Academy. The work must be printed, manuscript not being received, and in the event of its not gaining the prize will not be returned to its author. The Academy, I may further mention, reserves to itself the right to adjudge the prize to the savant whom it deems most worthy, even if he has not entered his name among the list of competitors. The prize has hitherto been the object of keen competition, and this will, in 1899, when the name of the successful candidate will be announced, be the eleventh award since its foundation in terms of the will of Dr. Cesare Alessandro Bressa.

The King and Dr. Baccelli.

King Humbert during Christmas week had been suffering from the familiar "cold in the head," or *costipazione di testa*, as Italians call it, and having, like all members of his family, a horror of posing as a "patient," let it run its course. On one of the last days of the year he went down for winter sport to the Latin shore, where he has a shooting-box at Castelporziano, near the site of the younger Pliny's villa, described incomparably by its *dilettante* owner. The day was very fine, the sun powerful, and His Majesty, still with the cold on him, was insufficiently clad. After some good sport in company with the Crown Prince the King, warm from the exercise and with a steady *tramontana* blowing, stopped to chat a little with an old gamekeeper just come back from South America. On returning to the Quirinal His Majesty felt he had paid for his imprudence, had several mild rigors, but would not "give in," and on the evening of the 30th ult. remained standing while receiving in audience the corps diplomatique till past midnight. On the morning of the 31st he wanted to get up to hear the customary report of his Ministers, but General Ponzio-Vaglia saw him just in time, noticed that he was still a prey to the rigors of the day previous, and prevailed on him to keep his bed. He would, however, see no one but the Queen, who remained beside him all day, at the end of which his state was such that the usual receptions of the Capo d'Anno were countermanded. By this time telegrams poured in from every European capital, the Emperor of Germany wiring twice, in affectionate urgency, for information. On the morning of the 1st inst. His Majesty's self-denying ordinance was overcome, he consented to see his physician, and, accordingly, Dr. Baccelli was in attendance at the Quirinal. The King smiled as he rose in bed to greet his medical adviser, saying, "Badi, onorevole Baccelli, che io la ricevo come amico, non come medico, perchè, grazie a Dio, sto bene, checchè ne dicano i giornali" ("You see, honourable Baccelli, I receive you as a friend, not as a physician, because, thank God, I am well, whatever the newspapers say"). The physician and ex-Minister, equal to the occasion, replied that his visit was not professional, but only to wish His Majesty a happy New Year. The King, however, detained him at his bedside for nearly half an hour, during which Dr. Baccelli (incidentally, of course) diagnosed the malady to be "rheumatic febricula," which with due attention to the "ingesta" would pass off in from two to three days, provided His Majesty kept his bed. The advice was taken; the prognosis has proved correct; no bulletin has had to be issued; and all the rumours as to the King's suffering from "pleuritis," or "pneumonia," or worse have not sufficed to cause a flutter on the Bourse.

Jan. 4th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Quarantine against Plague.

THE continued reports of plague at Bombay and the exit of 200,000 people from that city have excited no little interest in Egypt, for it is not forgotten that this country was once its headquarters. It is true that there has been no plague in Egypt since 1845, but if it were accidentally re-introduced it might be even more difficult than was the case with cholera to eradicate it from its former haunts. No one knows quite why plague suddenly left Egypt, for it can hardly have been due entirely to the sanitary precautions of that day. Perhaps it was merely an extension of the eastward recession of the disease, which began in the latter half of the seventeenth century and helped, with other causes, to free Europe from its ravages. Quarantine may be quite unnecessary in England, protected by its insular position and by the millions spent upon the country's sanitation, but one cannot help feeling that Egypt is still somewhat like a powder magazine from which the tiniest spark has very jealously to be excluded. The quarantine regulations of 1878 against plague have just been revised by the International Board in Alexandria. In accordance with modern notions ships are divided into three classes—clean, suspected, and infected. In the case of clean ships coming from a plague-stricken port seven days must have elapsed, linen and bedding must be disinfected, and drinking-water must be renewed. Suspected ships are defined as those on which there has been plague, but not for the last nine days. Ships carrying a medical officer and a disinfecting stove will be allowed to traverse the Suez Canal in strict quarantine, while other ships will be kept long enough to disinfect clothes and personal effects and to satisfy the sanitary officer that there are no fresh cases on board. Passengers destined for Egypt will be kept under observation for two days while their effects are disinfected. Lastly, there are the infected ships, meaning those which have had a case of plague on board during the last nine days. Passengers suffering from plague must be isolated in a hospital on shore. Healthy passengers are to be divided into small groups and kept in quarantine long enough to allow eleven days to have elapsed since contact with the last case. The whole ship and its contents are to be disinfected, and, as in all other cases, the drinking water is to be renewed and the bilge water disinfected and discharged.

Quarantine against Cattle Diseases.

Recent science has made the regulations of 1881 somewhat archaic, and after three years' anxious deliberation the representatives of the Powers have now agreed on all vital points and the new measures have been applicable since Dec. 1st. The regulations against cattle plague have been made more severe and include for the first time sheep and goats. Horses and mules suspected to be suffering from glanders or farcy will be inoculated with mallein before being admitted into the country. The other chief diseases from which Egypt desires to be guarded are charbon, pleuro-pneumonia, foot-and-mouth disease, sheep pox, swine fever, and scabies.

The Lunatic Asylum.

The number of patients here has lately been reduced from 480 to 420, chiefly because many quiet patients have been allowed to go home to their friends. All the inmates are now kept out-of-doors all day, except those who are actually confined to their beds in the infirmary. Nearly five acres of desert land adjoining the asylum has already been annexed and probably more will be wanted by the Government in the future. Among recent improvements carried out this year a modern system of locks and keys has been fitted, with necessary master keys, a lift for food has been built, and a second bath-room specially for female patients has been opened. Ventilation has been further improved, some 300 new windows have been made, and many of the old apertures have been glazed to keep out the winter cold. New drains and cesspools outside the grounds are now being finished. The extra space provided by the new wards and the airing courts has already resulted in a considerable diminution in the number of accidents to patients. The gradual improvement in the treatment of excited patients since the English occupation of Egypt is noteworthy. All troublesome patients used to be manacled for years together both by day and night. Camisoles were substituted for chains in 1884, though this was considered by the native medical men to be a dangerous proceeding. A padded room was built later, and the resident physicians trusted chiefly to narcotics to tranquillise the excited. Now the padded room has been done away with, the camisoles have disappeared, and narcotics are very rarely employed. Better results are now obtained by means of outdoor occupation and exercise. Dr. Warnock's reforms, effected in less than two years, have elicited the highest praise from all English visitors, and it is greatly to his credit that his work of reformation has been carried on without European assistants and even without

Hosted by Google

any regular interpreter. It has long been known that general paralysis is rare amongst Egyptians, but when all lunatics came to be examined by an expert the disease was not infrequently found. At the present moment there is a room full of general paralytics, and in the year 1895 seventeen males and two females were admitted to the asylum, and of these nineteen paralytics fourteen were Egyptians. Another interesting point for English observers is that the number of cases of melancholia admitted in Egypt into the asylum is about five times less than the number under similar circumstances admitted in England.

Cairo, Dec. 28th, 1896.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Difficulty at the Adelaide Hospital.

IN a former communication[1] it was stated that the house surgeons at the Adelaide Hospital had resigned and their resignations had been accepted by the board of management, but that no details had been made public. The proceedings of the board on this matter and also in the inquiry into the charges made by Dr. Leith Napier against Professor Watson have been presented to the House of Assembly and printed. In resigning the resident staff charged Dr. Leith Napier with incompetence, but when called before the board individually declined to give evidence except as a body and when all were present, and in consequence the board accepted their resignations. Subsequently a Select Committee of the Legislative Council was appointed to inquire into the affairs of the hospital, and after some preliminaries examined Dr. Cecil Corbin, one of the late resident surgeons, who was dismissed by the board. He explained that the refusal to give evidence before the board was due to the conviction of the resident surgeons that the board, as constituted by the Government, was not an impartial tribunal, but would uphold Dr. Napier and Dr. Ramsay Smith, and as the sittings were held in private the residents would have no corroboration of their statements. Dr. Corbin charged Dr. Leith Napier with performing operations unskilfully; with coming to a decision about operations incorrectly; and with ignorance of the nature of the cases and the proper treatment necessary. He instanced, among others, a case of supra-pubic lithotomy in which the peritoneum was opened and the operation generally bungled, the patient dying from peritonitis; a case of hydatid of the liver diagnosed as multiple hydatids and treated by a large abdominal incision away from the tumour, thus allowing escape of the cyst contents into the peritoneal cavity; a case of supposed renal calculus, in which the abdomen was opened in the middle line and the left kidney dragged out through the incision and cut into, no stone was found, and Dr. Napier was proceeding to do the same with the right kidney when Professor Watson interfered; a case of amputation of the forearm, in which damaged tissues were left and the bones cut too long, and more bone had to be taken away; and another case, that of a man with a lump under the tongue, which Dr. Napier diagnosed as "rhinolith" and cut into, but found no stone, the case being probably cancer. Of course, these are only Dr. Corbin's statements, and Dr. Napier has not given his version yet. The charge made by Dr. Napier against Professor Watson, of misrepresenting a case that occurred in the hospital, was investigated by the board of management in public. The case was that of a woman aged fifty years with a femoral hernia and symptoms of strangulation. Dr. Napier asked Professor Watson to operate, but he declined. Mr. Shepherd then operated, assisted by Dr. Napier, Professor Watson looking on. The sac was found to be filled with omentum, and Mr. Shepherd and Dr. Napier passed a finger into the crural canal and could feel no bowel. A portion of the omentum was ligatured and cut off and the wound closed. The patient died. Professor Watson, meeting Dr. Rogers, a member of the board, just after the operation, expressed his disbelief in Dr. Napier's surgical competence and asked him to be present at the post-mortem examination, as he was certain that the patient would die, the strangulation not having been relieved. As to what was found at the necropsy statements differ, Dr. Napier alleging that Professor Watson's description was incorrect and that the professor attempted to mislead the spectators and misrepresent the actual facts. Professor Watson's statement is that he found the omentum fastened by sutures to the margin of the saphenous opening, adherent to the sac, and tightly stretched over the small intestines, and a loop of small intestines fifteen inches long bound down and strangulated by this omental band, which had not been freed from its attachments to and in the neck of the sac at the operation. Professor Watson, before making the necropsy, stated that he expected to find a knuckle of gut strangulated at the crural ring, and this condition he admitted was not found. Dr. Napier asserts that there was no obstruction of the bowel, and that no further operative interference was required, while Professor Watson asserts that the operation was incomplete, no attempt having been made to release the adherent omentum or pass a finger into the peritoneal cavity and discover the real condition. Dr. Ramsay Smith supported Dr. Napier's statements as to the result of the necropsy, as did also Mr. Shepherd, the operator, and Dr. Hill and Dr. Rogers, members of the board. Subsequently, Professor Watson, who was suffering from a severe cold and unable to speak, requested that he might be represented by counsel to cross-examine the witnesses and that he might call the students who were present at the necropsy and might call expert medical evidence on his behalf. These requests were refused and the board decided that Professor Watson misrepresented the facts concerning the operation, and that his action in doing so was ill-judged; that the operation was skilfully performed by Mr. Shepherd, assisted by Dr. Napier; and that the post-mortem examination fully justified the treatment by the operators. The board was of opinion that Professor Watson's remarks had been most unjust to Dr. Napier and that the best interests of the hospital required that Professor Watson be requested to immediately resign his position as honorary consulting surgeon and pathologist.

[1] THE LANCET, Nov. 7th, 1896.

Unskilful and Horrible Treatment by a Midwife.

Margaret Grainger, a midwife, was found guilty of manslaughter and sentenced to penal servitude for five years at Rockhampton, Queensland, on Sept. 15th. The facts elicited at the trial were that Grainger attended a Mrs. Day in her confinement. The labour was normal, but the placenta not coming away the midwife attempted to remove it by pulling on the cord and inverted the uterus. Still dragging on this, which she mistook for the placenta, she tore the uterus away, and the woman died from hæmorrhage and shock. The judge, in addressing the prisoner, said that the case was the most dreadful and horrible in the criminal records of the colony and that the prisoner had shown the grossest ignorance. The prisoner had acted as midwife for thirty years both in India and Queensland, and in consequence of her age the sentence was not so heavy as the judge said he would have imposed had she been a young woman.

Insanity in New South Wales.

The report of the Inspector-General of the Insane for New South Wales for 1895 shows that on Dec. 31st, 1895, there were 3720 insane persons under official cognizance, an increase of 133 during the year. Dr. Manning states that the causes which led to the unusual increase during 1892, 1893, and 1894, appear to have been still in operation in 1895. The chief moral causes of insanity during 1895, as far as can be ascertained with accuracy, were:—mental anxiety, worry, and overwork; domestic trouble; and adverse circumstances, including pecuniary difficulties. The chief physical cause was intemperance in drink. The cost to the State for each patient was £24 6*s.* 4*d.*

Leprosy in New South Wales.

The report for 1895 of the New South Wales Board of Health upon the administration of the Leprosy Act has been presented to Parliament. At the beginning of 1895, 40 persons were under detention at the lazaret. During the year 10 persons were reported to the Board as suspected lepers, and three of these were eventually detained. Five patients died and one was discharged.

A Hospital Medical Officer charged with Assault by a Hysterical Patient.

Dr. Sheldon of the Sydney Hospital was sued for £30 damages for assault at the Sydney District Court on Nov. 12th. The plaintiff, a girl slightly under twenty-one years of age, stated that from childhood she had been subject to fits and went to the Sydney Hospital for treatment. While waiting in the out-patient room she fainted, and Dr. Sheldon came to her and pressed her forehead with much

Hosted by Google

severity; she ran away, but was brought back by the doctor, who applied the electric battery and otherwise ill-used her. She suffered great pain at the time and had never been well since. Dr. Binnie, the medical superintendent, the porter, a nurse, and a constable gave evidence that the girl was suffering from hysteria and was violent and that nothing but the ordinary treatment was used. The verdict was for the defendant.

Successful Operation for Intra-peritoneal Rupture of the Bladder.

In the November number of the *Australasian Medical Gazette* Dr. Charles Ryan records a case of intra-peritoneal rupture of the bladder. The patient, when drunk, had been wrestling and was taken to the lock-up. While there he became very ill and was removed to the Melbourne Hospital, where six ounces of blood-stained urine were drawn off with a catheter. The lower abdomen was very tender and efforts to pass urine were futile. Abdominal section was performed seventeen hours after the accident. The peritoneal cavity was full of blood-stained fluid, and a rectangular tear four inches long was found in the upper part of the bladder. This was closed with a continuous suture of fine chromicised cat-gut and the peritoneum thoroughly flushed out. Perineal section was performed and the abdominal incision closed. The bladder was drained for sixteen days by a tube through the perineal wound and recovery was uneventful. Dr. Ryan believes this to be the first case of the kind brought to a successful issue in Australia.

Excision of the Clavicle.

At the last meeting of the Victoria Branch of the British Medical Association, Mr. F. D. Bird read notes of two cases in which he had excised the clavicle. The first was for sarcoma of that bone and the second was to gain access to an exostosis of the first rib. Both cases were successful and the patients had remarkably good movement of the arm, and in the second case a new clavicle had formed from the periosteum which was left.

Ankylostomiasis.

Dr. L. N. Ashworth read before the Medical Society of Queensland the notes of a typical case of ankylostomiasis completely cured by large doses of thymol, and in the discussion which followed Dr. Jefferis Turner stated that every case of this affection treated properly by this method at the Brisbane Children's Hospital had recovered; but it should be understood that the treatment must be carried out in the right way. Repeated small doses did no good and probably accustomed the worms to the drug so that subsequent large doses failed. The correct method was to empty the upper bowel by preliminary low diet and purgation and then to give a dose of thymol sufficient to kill the worms, no solid food being given on the day of treatment, the excess of drug and dead worms being removed by a saline aperient.

Nov. 24th, 1896.

Obituary.

JOSEPH BARTON CARTER, L.R.C.P. EDIN., M.R.C.S. ENG., L.S.A.

A LARGE circle of friends have learned with regret of the death on New Year's Day of Mr. J. B. Carter of Chapel-Allerton, Leeds. Mr. Carter, who qualified in 1849, was one of the oldest practitioners in Leeds. He was born in Beverley, to which place his father (who served under Lord Nelson as a surgeon in 1803) had retired. For nearly half a century Mr. Carter conducted an extensive practice in North Leeds and his loss is keenly felt by all classes of patients. His kindly, hearty manner endeared him to all and his ready sympathy and sound advice caused him to be regarded as a friend to be relied upon in all emergencies. His long hours of professional work sat but lightly on him and did not prevent his keeping up a close acquaintance with the Latin and Greek authors with which in his earlier days he was so familiar. Many who read these lines will recall occasions when amongst his professional brothers he would quote line after line of the classics as bearing upon the subject under discussion. Wonderful as it is to us nowadays, here was a man working hard in general practice, who still kept up his classical knowledge. A widow, three daughters, and three sons survive him. Two of his sons were associated with him in practice and one, also in the profession, is in practice at Shipley. Only those who knew Mr. Carter will feel how his death has made a gap in the profession not to be easily filled. He was a man liberal in hospitality, unsparing in kindness, at once a "doctor and a friend."

JOHN LEITCH, M.B., C.M. EDIN.

ON Dec. 22nd, 1896, at the early age of forty-seven years, John Leitch died at Silloth, Cumberland. As late as Dec. 19th he had been seeing patients, although quite unfit to do so by reason of cardiac failure, for which he had been under treatment. His death came as a shock to all his friends and patients. Dr. Leitch was born at Monimail Manse, his father being then parish minister of Monimail in Fife. Educated at Merchiston Castle School and the Edinburgh Academy he studied at the arts classes in St. Andrews University before going to the medical classes in Edinburgh, where he took his degree in 1871. He afterwards went several voyages to America as medical officer in the Cunard Line and later became resident surgeon at Leith Hospital. In 1872 he settled down at Silloth and remained there until the end. For many years Dr. Leitch was medical officer to the Silloth Convalescent Institution, and amongst other interests he took an active part as chairman of the School Board. His great hobby was botany, and he spent the whole of his spare time, both as a student and afterwards, in the pursuit of botanical researches. This led him to leave Silloth every year, and sometimes twice a year, for a month or more, travelling through Scotland, England, Ireland, and the Channel Islands on foot and examining the flowers of the different districts. His collections of plants are in many respects unique and perfect, and he was well known as an authority on botany. Dr. Leitch never cared to bring himself forward and never published anything other than short notes and contributions to journals, and these often anonymously. He was fond of travelling, and spent some time in Russia and Norway, where he pursued his favourite study. Dr. Leitch married a daughter of the late Rev. J. Redford of Silloth. Seven children survive him, the youngest being two years of age.

Medical News.

UNIVERSITY OF OXFORD.—At the examination for medical and surgical degrees in the Michaelmas term, 1896, the following gentlemen were successful in the subjects indicated:—

FIRST EXAMINATION.

Materia Medica.—J. M. Fortescue-Brickdale, Christchurch; A. F. S. Kent, Magdalene; C. R. Moss, Keble; and S. Wellby, Trinity.

Anatomy and Physiology.—H. W. Crowe and H. S. French, Christchurch; F. O. Stoehr and S. Wellby, Trinity; and J. A. Willett, University.

SECOND EXAMINATION (M.B. EXAMINATION).

H. G. L. Barlow, Trinity; A. A. Bathe, Christchurch; W. Bosanquet, New; J. S. Fairbairn, Magdalene; J. C. Fisher, Brasenose; A. L. Ormerod, New; W. Ramsden, Pembroke; J. B. Tombleson, Corpus Christi.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bucharest:* Dr. Buiciiu has been appointed Professor of Clinical Medicine.—*Budapest:* Dr. A. Landauer has qualified as *privat-docent* in Physiology.—*Clausenburg:* Dr. Koloman Hönez and Dr. Gerhard Rudas have qualified as *privat-docenten* of Odontology.—*Christiania:* Dr. Laache has been promoted to the ordinary professorship of Internal Medicine.—*Lille:* Dr. Surmont has been appointed to the chair of Hygiene.—*Giessen:* Dr. Robert Sommer has been promoted to the ordinary professorship of Psychiatry.—*Heidelberg:* Dr. Franz Nissl has qualified as *privat-docent* in Neurology.—*Tübingen:* Dr. Dennig has been appointed Professor of Internal Medicine.

PORTSMOUTH HOSPITAL SATURDAY.—The result of the Hospital Saturday collection at Portsmouth this year has established a record, the total sum available after paying all expenses being £1095. Of this the sum of £1030 goes to the hospitals, £15 to each of four other institutions, and £5 to a sixth.

Hosted by Google

BIRKENHEAD MEDICAL SOCIETY.—At a meeting of the above society on Dec. 11th, 1896, Dr. Sidney Marsden, president, being in the chair, Mr. Francis Johnson read notes and showed photographs and charts of the following cases;—1. Hydrops Articuli of both Knee-joints in an otherwise healthy child, treated successfully by tapping and elastic pressure. Mr. Shears drew attention to the fact that hydrops articuli is frequently seen in children suffering from congenital syphilis. 2. Lupus of the Nose and Face treated by scraping and thyroid gland and followed by great improvement. 3. A case of Herpes affecting the area of the Scalp supplied by the left great and small occipital nerves. 4. A Sporadic or Myxœdematous Cretin greatly benefited by thyroid gland. This case gave rise to an interesting discussion on rhe methods of administering the thyroid gland. Dr. Blood showed a set of gall-stones removed by operation from a patient who had suffered from symptoms for twelve years.

FOOTBALL CASUALTIES.—In a football match at Bristol on Dec. 25th, 1896, between St. George's and Wamley, a member of the latter team fractured his clavicle.—During a match at Weston-super-Mare on Dec. 26th, between Weston-super-Mare and Cardiff Harlequins, a member of the former team fractured his clavicle.—While a local team called the Sun Albion were playing a game at Llanerchrugog-park, Ruabon, on the 25th ult., a youth aged seventeen years (right half-back) received a severe injury to the abdomen, and was removed to his home, where he died the next day.—During the progress of a match between the Lincoln Lindum team and eleven Christmas visitors, at Lincoln, a player sustained a fracture of the right ankle.—In a match on the 31st ult., at South Shields, between the Westoe and Harrogate Rugby fifteens, a Harrogate forward sustained an injury to his right leg and was removed to the South Shields Infirmary.—While playing in a match on Saturday last at Hebden Bridge against Castleford one of the home team forwards fractured his skull and was taken to the Halifax Royal Infirmary.—A half-back, of Beeston Hill, who was injured six weeks since while playing in a match, is now lying in an unconscious state at the Leeds Infirmary, suffering from concussion of the brain.—On Saturday last, during a match between Great Harwood and Blackburn Park-road teams, a player of the home team fractured his leg.—On the same day, in a match at Widnes, a player fractured his leg; and in a match between the Shipley and Menston clubs a player, a left wing forward, sustained a fracture of the ankle.

DIPHTHERIA IN LONDON.—During the two weeks ended on Saturday, Dec. 26th, the deaths registered from diphtheria in London showed considerable difference in the sum total per week. In the first of the two weeks the deaths numbered 58, as against 48, 60, and 52 in the three weeks preceding, the 58 deaths being 18 in excess of the corrected decennial average for the fifty-first week of the period 1886–95. Of the 58 deaths, 10 belonged to Camberwell, 6 each to Lambeth and Islington, 4 to Shoreditch, and 3 each to Fulham, Chelsea, Mile End Old Town, Poplar, and Battersea sanitary areas. All but 2 of the deaths were of persons aged from one to twenty years. On the closing day of the week, Dec. 19th, there remained in the London hospitals 838 patients suffering from diphtheria. In the succeeding week, including the Christmas holidays, the registered deaths from the disease fell to 38, this total being 4 below the corrected decennial average for the week. Four of the deaths belonged to Lambeth, 3 each to St. Marylebone, Islington, and Bermondsey sanitary areas. On Saturday, Dec. 26th, 850 patients suffering from diphtheria remained in London hospitals, the admissions in the week having numbered 129. During the fortnight the deaths registered from the disease in Outer London amounted to 24, of which 12 were of persons belonging to the West Ham registration district. Thus, in Greater London in the two weeks the deaths registered from diphtheria were 120 in number. In the concluding week of the the year ended on Saturday last—the year 1896 having, for registration purposes, fifty-three weeks—the deaths registered in London as due to diphtheria rose again to 49, and were 7 above the corrected average. Islington, Lambeth, and Camberwell were each of them credited with 5 deaths, and St. Pancras and Poplar sanitary areas, each with 3 deaths. The patients in hospital on Jan. 2nd numbered 845, there having been 115 admissions during the week. The same excess of fatal incidence in the ages one to twenty years was witnessed, as is now usually seen. Outer London suffered heavily in the week, 22 deaths having been registered, of which 11 occurred in the West Ham, 4 in the Edmonton, and 3 in the Hendon registration districts, making an aggregate of 71 deaths in Greater London.

THE DIFFUSION OF SMALL-POX.—There was an entire absence of fatal small-pox in London during the fourth quarter of the past year, but three admissions to hospital were chronicled in the closing week of the year, these three patients alone remaining under treatment on Saturday last. At Redruth the epidemic seems to be quite at an end, no fresh case having been reported since mid-December, the end of the year finding only some ten patients in hospital. At Cadoxton three cases of small-pox were last week sent to hospital, the patients being the keeper of a lodging-house, his wife, and child. Importation of the disease to the house in the person of a sailor is thought to have been the probable source of infection. The cases are said to be of mild character.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

AYMER, JAMES, M.B., C.M. Aberd., has been re-appointed Medical Officer of Health by the Johnshaven Parish Council.

BENNETT, WILLIAM EDWARD, F.R.C.S. Eng., has been appointed Resident Surgical Officer to the General Hospital, Birmingham, vice C. Leedham-green.

CARRUTHERS, D. A., M.B., C.M. Edin., has been appointed Medical Officer for the Parish of Kinnoull, Perth.

EVANS, CHAS. W., M.D. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Bakewell Urban District Council.

FORBES, DUNCAN M., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health, by the Eastwood Urban District Council.

FRANEY, EDWARD, M.R.C.S., has been re-appointed Medical Officer of Health by the Banbury Rural District Council.

GOLLAND, A., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the Altrincham District Council.

GREEN, C. DAVID, M.D. Lond., B.S., F.R.C.S., L.R.C.P., D.P.H., has been re-appointed Medical Officer of Health by the Edmonton Town Council.

HANSON, E. R., L.R.C.P. and S. Edin., has been appointed Medical Officer of Health for the No. 8 Sanitary District of the South Molton Union.

HARKER, W. E., M.D. Durh., B.S., has been re-appointed Medical Officer of Health by the Tyne Port Sanitary Authority.

JONES, FRED. F., M.R.C.S., D.P.H., has been re-appointed Medical Officer of Health by the Llanfyllin Urban District Council.

KEER, J. C., M.R.C.S., has been appointed Medical Officer for the Workhouse and the Wickham Market Sanitary District of the Plomesgate Union, vice G. Keer, resigned.

KNAPP, E. M. M., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the Ross Rural District Council.

LLOYD, DAVID, M.B., C.M. Glasg., has been appointed Medical Officer for the Llanrhaiadr Sanitary District of Ruthin Union, vice J. Caithness.

MAC LENNAN, DONALD U., M.D., C.M. Edin., has been re-appointed Medical Officer of Health, by the Widnes Town Council.

MAPLETON, G. H., M.B., C.M. Edin., has been appointed Medical Officer by the Cranbrook Board of Guardians.

MARSH, J. H., M.R.C.S., L.R.C.P., has been appointed Medical Officer and Ambulance Lecturer to the Macclesfield School Board.

PARKINSON, THOS. W., M.B., C.M. Edin., has been re-appointed Medical Officer of Health by the Edzell Parish Council.

PEPPER, H. W., M.R.C.S., L.R.C.P., has been appointed Assistant Medical Officer to the Workhouse Infirmary, Birmingham.

PURVES, A. S., M.D., C.M. Edin., has been re-appointed Medical Officer for the Lesbury Sanitary District of the Alnwick Union.

SMYTH, WM. A., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Sanitary District of Ashstead, Surrey.

SPRENT, W. S., L.R.C.S., L.R.C.P. Irel., has been appointed a Deputy Medical Officer by the Helmsley District Council.

TEMPLE, G. H., M.B., C.M. Edin., has been appointed Medical Officer of Health for the Weston-super-Mare Sanitary District of the Axbridge Union, vice V. Hitchins, resigned.

THOMAS, EVAN C., M.B., C.M. Edin., has been appointed Medical Officer of Health by the Lampeter (Cardigan) Rural District Council.

WALLIS, PERCY E., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the East Grinstead Urban Council.

WEBB, HENRY L., M.R.C.S., has been appointed Medical Officer of Health for the Cheadle Rural Sanitary District.

WEST, GEORGE F., L.R.C.P., L.R.C.S. Edin., has been appointed by the Lord-Lieutenant, Resident Medical Superintendent to the Kilkenny District Lunatic Asylum.

WILDE, L., M.D. Durh., L.R.C.P. Lond., M.R.C.S., D.P.H. Glasg., has been re-appointed Medical Officer of Health for Bedfordshire.

WILLIAMS, WALTER C., has been appointed Analyst for the Blackburn County Borough.

WYLLYS, HENRY J. M., L.R.C.P., L.R.C.S. Edin., has been appointed Junior House Surgeon to the Norfolk and Norwich Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—District Surgeon.

CLEOBURY MORTIMER, ROCK, TENBURY AND BURFORD RURAL DISTRICT COUNCILS.—Medical Officer of Health for the above districts for three years. Salary £75 per annum, to include travelling and all other expenses. Applications to the Clerk, Cleobury Mortimer.

COUNTY ASYLUM, Rainhill, near Liverpool.—Assistant Medical Officer, unmarried. Salary commences at £100 per annum, with prospect of increase to £250, together with furnished apartments, board, attendance, and washing.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge road, S.E.—Senior Resident Medical Officer. Salary £70, with board and washing.

FLINTSHIRE DISPENSARY.—Resident House Surgeon. Salary £120 a year, with furnished house, rent and taxes free, also coal, light, water, and cleaning, or in lieu thereof the sum of £20 per annum. Applications to the Secretary, Board-room, Holywell, North Wales.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Physician.

LINCOLN GENERAL DISPENSARY.—Resident Medical Officer for two years. Unmarried. Salary £150 per annum, with furnished apartments, coals, and gas provided.

MIDDLESBROUGH NEW ASYLUM.—Medical Superintendent. House (unfurnished, with rates and taxes free), coal, gas, water, and washing will be allowed. Salary required to be stated.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Resident Medical Officer for six months. Salary £30 per annum, with board, attendance, and washing.

QUEEN'S HOSPITAL, Birmingham.—Third Casualty Surgeon for three years. Honorarium £50 per annum. Also Second Physician for Out-patients, for three years. Honorarium £50 per annum.

ROYAL ALBERT HOSPITAL, Devonport.—Assistant House Surgeon, for six months. Board, lodging, and washing provided.

ROYAL HANTS COUNTY HOSPITAL, Winchester.—Assistant House Surgeon. Salary at the rate of £20 per annum, with board and lodging.

ST. GEORGE'S HOSPITAL, London, S.W.—Physician and Assistant Physician.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—House Surgeon. Salary £100, with board and residence.

UNIVERSITY OF EDINBURGH.—Examiners.

VICTORIA HOSPITAL FOR SICK CHILDREN, Queen's-road, Chelsea, S.W.—House Physician for twelve months. Honorarium £50, and board and lodging in the hospital provided.

Births, Marriages, and Deaths.

BIRTHS.

AUDLAND.—On Dec. 30th, at Oxford-street, Wellingborough, the wife of W. E. Audland, M.R.C.S., L.R.C.P. Lond., of a son.

CAMERON.—On Jan. 5th, at Elms-road, Clapham-common, S.W., the wife of Albert Cameron, M.B., C.M. Edin., of a daughter.

DAVIES.—On Jan. 5th, at Finsbury-square, the wife of Arthur Templer Davies, M.D. Cantab., F.R.C.P., of a daughter.

HOWARD.—On Jan. 1st, at Walworth-road, S.E., the wife of John A. Howard, M.D. Lond., of a son.

ROGERS-TILLSTONE.—On Dec. 28th, at Ditton, Maidstone, the wife of J. M. Rogers-Tillstone, M.R.C.S., L.R.C.P. Lond., of a daughter.

STANLEY.—On Jan. 4th, at Brabourne, Kent, the wife of Hubert Stanley, M.B. Cantab., M.R.C.S., L.R.C.P., of a son.

SYKES.—On Jan. 3rd, at York-road, Birkdale, Southport, the wife of J. Herbert Sykes, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES.

BARTON—FOX.—On Dec. 23rd, at the parish church, Norbiton, Percy Frederic Barton, B.A., of Camb., M.R.C.S. and L.R.C.P., to Annie S. Fox, eldest twin daughter of the Rev. Henry Elliott Fox, Hon. Sec. of the Church Missionary Society.

FERGUSON—MALONE.—On Jan. 1st, at St. Peter's, Eltham-road, Lee, George Gunnis Ferguson, M.B., C.M., of Holmdale road, West Hampstead, N.W., to Ada Bertha, daughter of the late Captain Joseph Malone, V.C., Enniskillen Dragoons.

HACKEN—MASON.—On Oct. 29th, 1896, at St. Andrew's Church, Braidwood, N.S.W., by the Rev. J. S. Dobson, Helen S., third daughter of Frank Mason, Esq., J.P., of Yately, Braidwood, to J. Preston Hocken, M.D., M.R.C.S., L.R.C.P., L.S.A., J.P., of West Wallsend, N.S.W., eldest son of J. Hocken, Esq., Liverpool, England.

DEATHS.

CARTER.—On Jan. 1st, 1897, at Elm House, Chapel Allerton, Leeds, Joseph Barton Carter, M.R.C.S., L.R.C.P., L.S.A., aged 73 years.

LEITCH.—On Dec. 22nd, at Monimail, Silloth, Cumberland, John Leitch, M.B., C.M. Edin., aged 47 years.

JAMESON.—On Jan. 1st, at his residence, Knollys-road, Streatham, Thomas Jameson, M.D., R.N., aged 59.

MACGREGOR.—On Jan. 4th, at his residence, Pembridge-villas, Southfields, S.W., Surgeon-Lieutenant-Colonel Alexander Macgregor, Indian Medical Service, Retired.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

TUESDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (14th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (16th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (11th).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Communications:—Mr. H. L. Albert: Two cases of Transplantation, with a third case of Transplantation of a Root subsequently Crowned.—Mr. E. Balding, jun.: A Case of Retarded Eruption.—Mr. H. Baldwin: Cement and Amalgam Fillings. Papers:—Mr. A. Pearce Gould: Means taken to prevent subsequent Deformity after Excision of Portions of Lower Jaw.—Mr. J. H. Badcock: Copper Amalgam, its Merits and Demerits.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Bland Sutton: Wandering Spleens.—Dr. S. West: The Prognosis of Pneumothorax, with a series of Cases of Recovery.

TUESDAY (12th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. E. C. Kingdon and Dr. J. S. R. Russell: Infantile Cerebral Degeneration, with Symmetrical Changes at the Macula.—Mr. T. S. Ellis: On some Points in the Surgical Physiology of the Foot.

WEDNESDAY (13th).—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—5 P.M. Annual General Meeting. Report of the Morbid Growths Committee: (1) Sarcoma of Nose; (2) Spheroidal celled Carcinoma of Vocal Cord, and Perichondral Sarcoma of the Cricoid Cartilage; (3) Rapid Destruction of Face. Cases and Specimens:—Some Presentations to the Society from Dr. Lefferts (New York) and from the President.—Dr. Semon: (1) Demonstration of Dr. Betz's plaster-of-Paris models of the Nose and its Accessory Cavities; (2) (for Dr. Macintyre) Some new Skiagraphs relating to Laryngology and Rhinology.—Dr. St. Clair-Thomson (for Dr. E. Brown, Montreal): A Nasal Snare.—Dr. Kanthack: Demonstration of some Morbid Specimens—(1) Microscopic and (2) Macroscopic.—Dr. P. W. Williams (Bristol): Case of Unilateral Abductor Paralysis in a Medical Student.—Mr. C. A. Parker: Unilateral Abductor Paralysis in a Boy.—Dr. W. Permewan (Liverpool): (1) Case of Double Abductor Paralysis in a Child; (2) Drawing of a case of Tubercular Ulceration of Larynx.—Mr. de Santi: A Man with a Pharyngeal Pouch.—Dr. J. M. Hunt (Liverpool): Drawing and Microscopic Specimen of Early Malignant Disease of the Larynx.—Dr. J. Horne: Dropping of Fluid (cerebro-spinal) from one side of the Nose. 7.45 P.M. Annual Dinner (Café Monico).

SOUTH-WEST LONDON MEDICAL SOCIETY (Town Hall, High-street, Wandsworth).—8.30 P.M. Mr. H. Marsh: Studies of Diagnosis in Difficult Cases, with illustrations.

HUNTERIAN SOCIETY (London Institution, Finsbury-circus).—8.30 P.M. Pathological Evening. Mr. Openshaw: Uterine Fibroid removed by Abdominal Hysterectomy.—Mr. Targett: Carcinoma of Body of Uterus.—Mr. F. J. Smith: Large White Kidneys. Other specimens will also be shown.

THURSDAY (14th).—SOCIETY FOR THE STUDY OF INEBRIETY (11, Chandos-street, Cavendish-square, W.)—4 P.M. Paper: Mr. J. J. Pitcairn: The Prison Treatment of Habitual Drunkards. Mr. E. T. Aydon-Smith will exhibit specimens of Japanese Opium Pipes.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Dr. Purcell: New Form of Intestinal Clamp.—Mr. Taylor (Birmingham): (1) Pan-hysterectomy by Kelly's method; (2) Sarcoma of Bladder. Annual Meeting.

FRIDAY (15th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-st., Cavendish-sq.).—8 P.M. Dr. Hamer: Age Incidence in Relation with Cycles of Disease Prevalence.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

TUESDAY (12th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—Dr. Buzzard: Clinical Demonstration.

FRIDAY (15th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—Dr. W. S. Colman: On Case-taking.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

AN "INCANTMENT."

To the Editors of THE LANCET.

SIRS,—To the various interesting remedies for diseases favoured by the medical fraternity in former times which have been published in the correspondence columns of THE LANCET the following, extracted from Herr Heim's recently published "Incantamenta Magica Græca Latina," may be worthy of a place: "Ad febres. Morionis manum unam collige cum oratione dominica, tere cum aquâ frigidâ, bibe, probatum est."

I am, Sirs, yours faithfully,

Jan. 4th, 1897. JOSEPH OFFORD.

AN EXTEMPORISED ARM BATH.

MR. RICHARD SLOCOCK, of Goldwell, Newbury, Berkshire, writes to us that a galvanised iron vessel called a "seed lip," used for holding seed and carried by a man who is sowing, makes an excellent arm bath for use in cases of poisoned hands or arms. Its shape is adapted to that of the body; it is not too deep nor does the edge hurt the arm. It is kept in stock by country ironmongers.

"THE UNQUALIFIED ASSISTANT."

To the Editors of THE LANCET.

SIRS,—I had hoped to see ere this an answer to "Student's" plea for the unqualified assistant, which appeared in THE LANCET of Dec. 16th, 1896. But as none has appeared may I venture to write a few words on the matter? I presume that the great fundamental moral objection to the employment of unqualified assistants is the undoubted, and often proven, fact that these assistants hold themselves forth, and are held forth by their employers, as being duly qualified men. The fact that they have failed in their examinations or that they have not yet received the minimum of instruction which would entitle them to sit for examination is most carefully withheld. They are therefore impostors, only less guilty than those who make money by employing them. "Student" protests against the unqualified man being prevented from earning his living by practising the profession which he hopes to enter, but to which he does not belong, and asks, "In what other profession in the world does such a state of things exist?" I venture to reply, "In every other profession." If a man took a curacy without having been ordained what does "Student" think would happen to him? If a law student acted as a solicitor without really being one he would certainly find himself in prison before very long, and "imagination boggles at" the idea of the fate that would befall the man who, not being a barrister, should assume wig and gown and "address the Court" in any but his own cause. Lastly, if a man presume to practise the "profession of arms" without due authority from some acknowledged potentate, he will find himself hanged as a murderer or shot as a filibuster. In medicine, and in medicine alone, Sirs, has the unfair competition of the unqualified man ever been tolerated. The law student may earn an honest pound or two by doing law clerk's work, the divinity student by, say, tutorial work; but neither may trespass one inch upon the field of the members of the respective professions. And so it should be with the medical student. Nobody objects to his acting as dispenser or to his keeping the books of some busy practitioner, but it is an outrage to the profession and a gross fraud upon the public that he should be allowed to visit and treat the sick. "Student," in my opinion, misrepresents the gentlemen who swell the ranks of the unqualified assistants. Here and there may, perhaps, be found one whose position is his misfortune, not his fault. But the very great majority of them are not worthy young fellows who, after a successful but all too brief career at a hospital, find themselves stranded through paternal indiscretions or disasters. They are mostly good-for-nothing idlers who, having dawdled away some eight or ten years pleasantly enough at a medical school, hear at last the just but terrible paternal fiat, "Earn your own living!"

I am, Sirs, yours faithfully,

Jan. 3rd, 1897. A PRACTITIONER.

M.B.—We do not consider the advertisement seemly, but hope that the medical men themselves are not responsible for it. The mistake in the description of the first gentleman named would seem to show that he had no knowledge of the matter.

ADVERTISEMENT.

WE understand from a correspondent that the following card has been publicly circulated:—

NORTH KENSINGTON DISPENSARY,
152, WALMER ROAD,
NOTTING HILL, W.

(Close to where the four roads meet: Walmer Road, Lancaster Road, Clarendon Road, and Silchester Road).

EXPERIENCED DOCTOR
At any Hour, Day or Night.

MINIMUM CHARGES.
(For Cash Down).

Midwifery...	10/6
Medicine	6*d.*
Medicine (3 times in a week)...	1/-
Visit	1/-
Visits and Medicine for a week	2/6

"Experienced Doctor" must know that it is unprofessional to press his claim upon the public in any way so as to attempt to undersell his fellow practitioners or detach their patients from them.

A WARNING TO MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me through your columns to warn the medical profession against an individual who is presenting cards bearing my name, and obtaining loans of a few shillings to, as he states, pay his fare home to Croydon, he having either lost his ticket or run short of money and he does not want to return to the office? He promises to repay the money next day but, of course, does not do so. I would point out that this person in no way represents me and is an impostor. Thanking you in anticipation,

I am, Sirs, yours truly,

WALTER MAYS,

Old Kent-road, Jan. 2nd, 1897. Cork Merchant and Manufacturer.

"DISINFECTION OF BOOKS AFTER SCARLET FEVER."

To the Editors of THE LANCET.

SIRS,—My attention has been directed to THE LANCET of Dec. 19th, wherein "A. B. S." asks for information on disinfecting books used during an attack of scarlet fever. During the epidemic of small-pox in Sheffield in 1887 the Corporation Free Library Committee found that books were often taken from the public libraries for the use of persons suffering from small-pox. As a result the issue of books was stopped for a time to prevent, if possible, the spread of the disease through the circulation of books from the libraries. A sub-committee was formed, of which I was a member, to consider the subject. The committee decided, after experiments, to have constructed a sheet iron oven about two and a half or three feet square, with an inner and outer chamber and a space of two inches between them. Within the two inch space and on the bottom of the oven a circle of Bunsen gas burners was inserted, which heated the air in the space surrounding and interior of the oven to from 180° to 220° F. On the bottom of the inner chamber was placed a small vessel containing No. 4 Calvert's liquid carbolic acid; the heat dissipated the acid into fumes, which penetrated the leaves and the whole texture of the books previously placed into the oven in an open state, resting upon their own front binding in grooved recesses. The oven had regulating dampers, a thermometer to register the heat, with flues to pass off both heat and fumes as generated into an adjoining chimney. Neither the leaves nor the binding were injured, and the result was most satisfactory and believed to be effectual. Since that time all books belonging to the free libraries of the city found in certified infected houses by the medical officer of health are notified to the city librarian. All are disinfected by passing through the carbolic oven before they are again issued into circulation. The oven and its appliances can be seen at the Free Central Library, Sheffield.

I am, Sirs, yours faithfully,

Dec. 30th, 1896. A LATE MEMBER OF THE SUB-COMMITTEE.

Inquirer.—If our correspondent can prove his case he ought to have no difficulty in recovering his fee against one or other of the parties in the county-court. We are not so clear as to the nurse, unless our correspondent is liable to pay, and has paid, her.

Ignoramus will find the exact information he requires in the Students' Number of THE LANCET, published on Sept 5th, 1896.

". . . . A SIMPLE CHILD THAT LIGHTLY DRAWS ITS BREATH."

UNLESS, as we suspect is the case, the "infant phenomenon" hereinafter described be the offspring of the American reporter's brain, the "phenomenon's" parents deserve the sincerest pity. The following details are reproduced by our contemporary the *Globe* from the *New York Journal*:—

"A BOY SURGEON.

"Though less than five years old little Will Gwin knows the name of every bone in the human body, knows the location of the various organs, and talks learnedly of the most intricate surgical operations. He knows more anatomy than most medical students. And not only this, but he can wield the scalpel as deftly as many surgeons. The boy's father is a physician and the little one almost always accompanies him on surgical cases. He has frequently seen the human body dissected, and has watched the gleaming knives at their gruesome work with intense interest. Frequently he has been with his father when called to attend persons mangled by the electric railways in New Orleans and has exhibited a boy's keen interest at so novel an experience. Once, when the injured man had been placed under the influence of chloroform, the boy looked up at his father and said, 'Papa, does God make chloroform so that people can be fixed not to feel the knife when the doctor uses it?' Again, the little fellow placed his hand in one of the gaping wounds and told the doctors his idea of the injury that had been inflicted.

* * * * * * *

Dr. Howell B. Gwin, the boy's father, explains how it happens that the child comes to know so much about anatomy. Dr. Gwin says: 'In romping with my boy on the bed I used to amuse him by calling out some difficult name of a bone in the body and taunting him with not being able to repeat it. He very readily caught the words and, strangely enough, retained them without any effort. He then began to associate the name of the bone with its location, and it was not long before he knew a great deal of anatomy.'

* * * * * *

Not so very long ago this youngest of all surgeons paid a visit to New York and thoroughly inspected the larger hospitals there, paying particular attention to the cases of interest in the surgical wards. He also took a look at the hospitals of Philadelphia, Washington, Cincinnati, St. Louis, and of other cities."

After this we can but express our sympathy with "little Will's" parents and commend him to the notice of Dr. Ibsen as a specimen of the younger generation.

Fair Play.—The demand for an addition to the salary would be reasonable, but we are not aware that any legal decision can be quoted in its support.

THE PREVENTION OF THREAD WORMS: A QUERY.

To the Editors of THE LANCET.

SIRS,—I should feel much obliged if any of your readers would kindly give me a permanent remedy for thread worms in a little girl seven years of age who has suffered from them for two years. Ordinary remedies are of only temporary relief as they recur again and again.

I am, Sirs, yours truly,

Jan. 4th, 1897. PERSEVERE.

Subscriber.—Alabone, Edwin William, registered as Mem. R. Coll. Surg. Eng. 1870. His name and qualification were erased from the Medical Register on Nov. 16th, 1886, by order of the General Medical Council in consequence of his name having been removed from the list of Members of the Royal College of Surgeons of England. There is no one on the current Medical Register bearing the name.

NATIVE SURGERY IN NEW BRITAIN.

THE Rev. John A. Crump, Wesleyan missionary in New Britain, has described in the *Auckland Weekly News* some extraordinary surgical operations performed among the natives of that Polynesian island and asserts that they are followed by very satisfactory results. Fractures of the tibia, both simple and compound, are treated by cutting away the soft parts, and removing any splinters of bone. Then a piece of the green taqete stalk (Cordyline terminalis) about four inches long, and half an inch in diameter is forced into the central cavity of the upper part of the broken bone for two inches of its length. The limb is then violently extended, the lower part of the bone fitted on to the projecting taqete stalk, and the two fractured surfaces thus brought together. A piece of the midrib of the cocoanut leaf is then securely tied over the limb, and in a very short time the patient is about again. Mr. Crump was not successful in his endeavours to ascertain what became of the piece of stick inside the bone. After depressed fracture of the skull the scalp is incised with a piece of shell or obsidian and the fragments of bone are picked out, perhaps leaving the brain freely exposed; the wound is then closed and dressed with bruised leaves and strips of banana stalk, and in a month recovery is complete. Mr. Crump obtained possession of several skulls which had been treated in this manner, all of them showing evidence of the commencement of new growth.

R. T.—We do not know anything of any correction of our statement. At all events what we said was right, and any contradiction of it is entirely wrong. The name is *not* upon the current official roll of the profession.

MASSAGE OF THE EYEBALL BY A QUACK.

A MUNICH quack who was brought up as a tailor was recently prosecuted for having caused damage to a patient with detachment of the retina by his treatment, which consisted in practising massage on the eyeball. In defence two other quacks who styled themselves *Naturheilärzte*, "natural cure doctors," were called, and these gentry affirmed that massage was by no means contra-indicated in retinal detachments. The court, however, preferred to accept the opinion of two well-known ophthalmic surgeons that the tendency to loss of sight had been increased by the manipulations of the prisoner, who was accordingly sentenced to a month's imprisonment.

Baynham.—The matter will receive our immediate attention.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Scottish Highlander, West Lothian Courier, Woking Mail, Newcastle Chronicle, East Anglian Daily Times, Glasgow Evening News, Bradford Observer, Indian Engineer, Times of India, Lowestoft Standard, Pioneer Mail, Banbury Guardian, Scotsman, Liverpool Daily Post, Manchester Courier, Dewsbury Reporter, Speaker, Carlisle Journal, Preston Herald, Builder, Rochester Journal, Cheltenham Herald, Architect, Somerset County Herald, Worcestershire Chronicle, Leeds Mercury, Sussex Daily News, Leicester Post, Essex County Standard, Liverpool Courier, Yorkshire Post, Hampshire Telegraph, Wolverhampton Chronicle, Surrey Times, Darlington Times, Bristol Mercury, Birmingham Post, Western Morning News, Durham Chronicle, Barnsley Chronicle, Cornish Telegraph, Devizes Gazette, Stratford Express, Sanitary Record, Weekly Free Press and Aberdeen Herald, The Morning, City Press, Reading Mercury, Hertfordshire Mercury, The Sun, Local Government Chronicle, Mining Journal, Local Government Journal, Surrey Advertiser, Heckmondwike Reporter, Yorkshire Weekly Post, Daily Chronicle, Exmouth Journal, The People, Buckingham Express, Galignani Messenger, Kentish Mercury, West Middlesex Herald, Prescot Reporter, Keighley Herald, Jackson's Oxford Journal,* &c, &c.

'Tabloids'

of

Animal Substances

Contain the whole of the gland or organ from which they are prepared, and consequently retain all the active constituents. In the absence of any known solvent of the whole of the active principles of these organs, extracts of medicinal animal substances must continue to be unreliable in strength, and in some cases dangerous owing to decomposition. Reports are continually appearing in the professional press confirming the scientific excellence of 'tabloids.' Many thousands of glands are worked in batches, and brought to a homogeneous mass and an average percentage of the active constituents is obtained. The dose can thus be regulated with the utmost certainty. Though certain of these organs have already proved of extreme value, many of them are still on trial, and 'tabloids' are made at the request of the profession for the purposes of clinical research.

UNDER EMINENT SCIENTIFIC CONTROL.

"APENTA"

THE BEST NATURAL APERIENT WATER

Bottled at the Springs, Buda Pest, Hungary.

"We know of no stronger or more favourably-constituted Natural Aperient Water." } *L. Liebermann*

Royal Councillor, M.D., Professor of Chemistry, and Director of the Royal Hungarian State Chemical Institute (Ministry of Agriculture), Buda Pest.

APPROVED BY THE ACADÉMIE DE MÉDECINE, PARIS.

THE LANCET says:—

"A much-esteemed purgative water."—"Its composition is constant. The practitioner is thus enabled to prescribe definite quantities for definite results."—"A Natural Water."

THE MEDICAL PRESS AND CIRCULAR says:—

"Belongs to that large class of aperient waters which come from the neighbourhood of Buda Pest."—"Contains a large amount of lithia. Specially marked out for the treatment of gouty patients."

THE EDINBURGH MEDICAL JOURNAL says:—

"One of the most valuable of aperient waters."—"Agreeable to take."—"Very efficient."—"Reliable in its therapeutic effects."

THE BRITISH MEDICAL JOURNAL says:—

"Affords those guarantees of uniform strength and composition which have long been wanting in the best-known Hungarian Waters."—"Agreeable to the palate."—"Exceptionally efficacious."

THE HOSPITAL says:—

"Must be regarded as the finest amongst natural aperient waters known."—"Should be taken systematically every morning in quantities of about three ounces. A valuable water for those of gouty diathesis, and for those who are afflicted with chronic inflammation or constipation."

THE BIRMINGHAM MEDICAL JOURNAL says:—

"Peculiarly rich in mineral salts, containing indeed a larger proportion of sulphate of magnesia than any other mineral water at present in the market, and also a better proportion of that salt to its other chief constituent, sulphate of soda."

The highly favourable reports published by the "Gazette des Hôpitaux," "Presse Médicale," "Progrès Médical," "Médecine Moderne," "Journal de Médecine," Paris, &c., will be forwarded on application.

Full Analysis, Additional Testimony, and Samples will be supplied on application to

ON
STUDIES IN DIAGNOSIS, ILLUSTRATED BY DIFFICULT CASES.

Delivered before the South-West London Medical Society on Jan. 13th, 1897,

BY HOWARD MARSH, F.R.C.S. ENG.,
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL.

GENTLEMEN,—In the daily routine of practice, whether in a hospital or elsewhere, there is only time for a careful examination of each patient and the selection of the treatment that is most likely to be efficacious; but on occasions of greater leisure—at such a meeting, for example, as the present—it may be useful to turn from individual cases to the subject of diagnosis as a whole and to inquire how it is that the mistakes which we all have to regret are so common as they are, and to endeavour to ascertain by what general considerations and rules of procedure they may as far as possible be avoided. When I received your invitation to read a paper this evening I thought it might be appropriate if I brought under your notice some studies in diagnosis illustrated by difficult cases. It need scarcely be said that diagnosis at the present day is more important than it ever was before, because upon the diagnosis formed will depend the treatment that is adopted, and treatment may involve very important operative procedures in the use of which it is highly desirable that no error should be committed.

1. *In some cases an accurate diagnosis is impossible, because the disease from which the patient is suffering is unknown; it has never been named, described, or even recognised.*—Doubtless there are still many such, just as a few years ago syphilitic affections of the joints, osteitis deformans, actinomycosis, and infantile scurvy were unknown. This source of failure in diagnosis steadily diminishes as a result of crucial clinical observation, laboratory research, and post-mortem examinations, but much remains to be done.

2. *Diagnosis may be practically impossible because the condition present is one which previous experience would not lead us to anticipate.*—This is illustrated by a remarkable case published by Mr. R. W. Parker.[1] Case 1 is that of a child twelve months old who, while being carried in the mother's arms, was attacked by sudden dyspnœa, as if there were a foreign body in the air passages. The mother, however, was sure that the child had not swallowed anything. Tracheotomy was performed, but gave no relief, and the child died in two hours. On post-mortem examination the symptoms were readily explained. An abscess had formed round some bronchial glands and had burst into the trachea just above its bifurcation, and through the resulting opening a caseous gland had slipped so as to project into, and almost occlude, the lumen of the trachea.

3. *Symptoms which would be characteristic, and which are generally present, may be absent.* Thus (Case 2) there is a renal calculus in the Museum of St. Bartholomew's Hospital of very large size. It was removed post mortem from a patient who had been in the hospital several weeks, but in whom no symptoms whatever suggesting renal calculus had been observed. In Case 3 a man aged sixty-seven years was recently admitted into St. Bartholomew's Hospital with "spontaneous fracture" of the right femur, which occurred as he was walking in a room. It seemed highly probable that the bone had been weakened by a new growth, but no enlargement could be detected at the seat of the fracture and no primary carcinoma could be anywhere found. He was in very feeble health and could take no solid food, but he swallowed fluid foods easily. He died from exhaustion in ten days. On post-mortem examination it was found that he had far advanced epithelioma of the œsophagus, yet, though he had been carefully watched, he had presented no symptoms whatever of this condition. He swallowed such food as he was able to take quite readily; there was no regurgitation and no pain. It may be interesting to mention that not very rarely, even in advanced epithelioma of the œsophagus, no difficulty in swallowing is present.

4. *The same symptoms may be produced by widely different conditions, so that the data for a differential diagnosis may be absent.*—This is illustrated in cases in which the question is whether the patient is suffering from stone in the kidney or tuberculous disease of that organ. (Case 4): In a young man aged twenty-three years the following symptoms were observed. Severe pain in the left lumbar region, extending down to the testis and the upper part of the thigh, and always aggravated by exercise, tenderness on pressure, blood and pus in the urine, and frequent micturition. In this case I believed that the patient probably had renal calculus, and one of the most sagacious physicians who have practised in London in recent years, and a surgeon of the highest authority in such cases, agreed with this view. But on exploring the kidney I found that the case was not one of renal calculus, but of tuberculous disease. Probably there is no other organ in the body the diseases of which present, by reason of the similarity of their symptoms, such difficulty of diagnosis as the kidney. Some years ago I met with the following remarkable case. (Case 5): A woman aged twenty-four years had the symptoms of renal calculus in the left kidney. When the kidney was exposed it was found to contain four or five small stones and to be extremely atrophied. It was therefore removed. A few months later the patient complained of severe pain in the right kidney and a small stone was passed with the urine. Soon after this her symptoms became much more severe. She had intense pain in the region of the right kidney, violent sickness, and faintness, and complete suppression, lasting for twelve, twenty, or even on some occasions for forty hours. On one occasion not a drop of urine came down into the bladder for fifty hours. This was clearly ascertained by the use of a catheter. After these periods of suppression she passed large quantities of urine mixed with blood. These attacks were often brought on by exercise. While she was lying in bed she was generally free from them. These symptoms were believed to indicate the presence of a calculus in the kidney, which became from time to time impacted in the orifice of the ureter. On two separate occasions the kidney was explored, but no stone was found. As the symptoms continued, and as two of the attacks had threatened to be fatal, it was determined once more to explore the kidney as thoroughly as possible. It was therefore exposed and opened and a long probe was passed down the ureter, but no stone could anywhere be detected. She died three days afterwards and on post-mortem examination it was found that she had fæcal extravasation, produced by rupture of adhesions around a former appendicitis. On examining the kidney it was found to be hypertrophied, but it structurally was perfectly healthy. The ureter was normal and no stone was present. It seemed clear, therefore, that the case was one of intense vaso-motor disturbance of the circulation, strongly resembling Raynaud's disease. The case was published in the Clinical Society's Transactions, vol. xxv., p. 195. In this instance the symptoms were completely misleading, and on looking back it seems difficult to see how the mistake could have been avoided.

In their early stage I believe it is not rarely impossible to distinguish between tuberculosis, osteo-arthritis, and syphilitic disease of the knee-joint; and in some cases even urethral arthritis affecting this joint may very strongly resemble tuberculous disease. (Case 6): A man aged twenty-six years was admitted into St. Bartholomew's Hospital with an affection of the knee of three months' duration. He was pale and thin. The joint presented swelling clearly mapping out the synovial membrane, which felt thickened and pulpy. Little or no fluid was present. The limb was flexed, the joint was painful and warmer than the other knee, and the muscles of the thigh were wasted. These appearances exactly corresponded with the view that the disease was tuberculous. It was found, however, that the patient had urethral discharge. The case was therefore treated as one of urethral arthritis, and in the course of two months almost recovery had taken place. Great difficulty is sometimes met with in forming a diagnosis between tuberculous caries of the spine and new growth, whether primary sarcoma or carcinoma secondary to primary disease elsewhere. The symptoms of caries and of new growth may be at first quite identical. (Case 7): Two years ago I saw a patient, aged forty-two years, with well-marked angular curvature in the mid-dorsal region. For five months she had been complaining of weakness of her back, gradually increasing difficulty of movement, and severe girdle pains. But the

[1] Transactions of the Clinical Society, vol. xxiv., p. 6.

Hosted by Google

symptoms which she presented differed in no particular from those of tuberculous caries till a few days before I saw her, when her left leg was noticed to be paralysed. On examination it was ascertained that she had carcinoma of the breast, and on being questioned said she had known of a swelling in the breast for eleven months. There was now extensive disease of the glands of the axilla. She died three months later with secondary deposits in the lungs and other internal organs. I would venture to remark that in any instance of disease of the spinal column, especially in patients of middle age, the presence of severe pain which is not relieved when the spine is kept at rest should raise the suspicion that the case is one of new growth.

5. *It is important to observe that though the salient or obvious symptoms may be common to quite different conditions, yet if we go a stage further and look more closely we often find in other symptoms or features of the case, which had at first sight appeared trivial, evidence that will guide us to a correct conclusion.* For instance (Case 8) a child aged ten years is lame, walks on his toe, complains of pain in his knee, has limited movement of the thigh upon the trunk, pain after exercise, and wasting of the muscles of the thigh. Moreover, it is observed that his pain is relieved by rest. Now these are all symptoms that are present in a case of hip disease, but they are also the symptoms of disease of the lumbar spine attended with iliac abscess. We have to ascertain, therefore, from which of these two conditions the patient is suffering. On proceeding further we may find some alteration of outline or some stiffness of the lumbar spine, together with a swelling in the iliac fossa, and we may further ascertain that the enarthrodial movement of the hip-joint within a limited range is quite free. He has, therefore, not hip disease, but disease of the lumbar spine.

Again (Case 9), a child aged five years was suddenly attacked with pain in the left lower limb, extending down the thigh to the knee. The limb was flexed, abducted, and rotated outwards; the child screamed when the limb was moved and his temperature was raised. The case, in the presence of these symptoms, was regarded as acute hip disease, but this conclusion was quite erroneous, for on close examination it was found that the hip-joint was quite freely moveable, and this symptom showed that the joint itself was unaffected. The case was now regarded as one of acute anterior poliomyelitis, attended with pain and fever. The ultimate course of the case completely confirmed this view. Take another example. A man aged forty years (Case 10) finds that his shoulder gradually becomes painful, especially at night, and he is unable to lie on that side. The joint becomes so stiff that he cannot dress himself or put his hand into his trousers pocket. Any movement or jar is extremely painful. The muscles around the joint become markedly wasted. A diagnosis is formed that he is suffering from rheumatic disease of the shoulder-joint. On critical examination, however, it is noticed that within a limited range the enarthroidal movement of the joint is perfectly free and smooth. This test proves that the shoulder-joint itself is free. The patient, in fact, is suffering from adhesions outside the joint, which produce all the gross symptoms of disease of the articulation itself, and it is only when we go a stage further, and observe that enarthroidal movement within a limited range is free, that a correct conclusion is arrived at. This example is worthy of attention in reference to the cases which bone-setters may cure. For the manipulative treatment of these adhesions outside the capsule is very much the same as that which bone-setters often adopt.

6. *Some very grave disease may be present, the symptoms of which are very slightly marked and are completely obscured by those due to some other condition.* For instance (Case 11), a girl aged fourteen years, whom I was seeing for hip disease, was constipated and her mother gave her an aperient. This was followed by severe abdominal pain. The bowels did not act, but there was persistent vomiting, followed by great exhaustion, almost amounting to collapse. The eyes were sunken and the countenance indicated great distress. These symptoms strongly suggested acute obstruction such as might be produced by strangulation of a loop of the small intestine by a band. But as the abdomen was quite free from distension and nowhere tympanitic, and as no localised swelling could be felt it was determined to postpone laparotomy, for which every preparation had been made. A few hours sufficed to show how fortunate it was that this course was adopted. The child proved to be suffering from acute tuberculous meningitis. It was to this that the urgent sickness was due. The pain was mere griping from the aperient. The collapse was produced by the constant vomiting. This case was extremely misleading, for at first there were no cerebral symptoms whatever to be observed. The child had no headache and no photophobia, convulsions, strabismus, slow pulse, or irregularity of the pupils.

7. *The circumstances under which the symptoms are developed may render them extremely deceptive.*—Thus (Case 12) a girl aged five years had been suffering for many months with discharge from the right ear. This discharge had ceased three weeks before her admission into the hospital. When she was first seen she was suffering from severe pain in the head, alternating with periods of partial unconsciousness. There soon followed convulsions, starting in the hand, but spreading so as to become general. There was retraction of the head and also great restlessness. The previous history of the case suggested that an abscess in the cerebellum or the temporo-sphenoidal lobe in connexion with ear disease had led to meningitis. The question of trephining was discussed, but as the convulsions had become general and there was such marked retraction of the head the operation was postponed. The child died a few hours afterwards, and on post-mortem examination it was found that the ear mischief was quite quiet and that the symptoms depended upon intercurrent acute tuberculous meningitis.

8. Every surgeon is familiar with cases of *nervous mimicry, or neuromimesis.* A notable case was in St. Bartholomew's Hospital three years ago (Case 13). A girl aged seventeen years was admitted with, as it was thought, hip disease. She had been treated by weight-extension for several months. The limb was so much adducted that there were three inches of apparent shortening. As the deformity of the limb was so marked she was placed under an anæsthetic in order that a thorough examination might be made, and the limb placed without the use of force in as favourable position as possible for further weight-extension. When she was asleep, however, it was found that the limb passed into a perfectly normal position and was freely moveable. This patient perfectly recovered under massage and electrical treatment, combined with the moral control exercised by the sister of the ward.

But neurotic patients may entrap the incautious practitioner into some serious error. In a spinal case, for instance, the surgeon finding that the patient is obviously neurotic, and forgetting the fact that the presence of neurotic symptoms cannot be taken as any proof that tuberculous disease is absent, may come to the conclusion that no caries is present. (Case 14): I lately saw a woman aged twenty years who was said to have merely a neurotic spine and dyspepsia. She was undoubtedly highly neurotic. It was, however, found that there was distinct, though slight, angular curvature at the level of the sixth dorsal vertebra; that the spine was somewhat stiff; that coughing produced sharp pain; that she could not stoop easily; that the pain in the pit of the stomach of which she complained was increased by exercise and relieved as soon as she lay down. It was clear, therefore, that the case was not one of mere neurotic spine, but that the patient was suffering from early spinal caries.

9. *Sometimes it may happen that there is some element in the case which is not taken into account.* (Case 15): Thus a patient returned from Burmah convalescent from typhoid fever, but with periostitis of the ribs which had gone on to suppuration. The abscess was opened, scraped, and drained. The patient seemed to be doing perfectly well up to the third day, when the temperature suddenly went up to 104° F. and he had a severe rigor, such as might suggest septic absorption; but as he had been in Burmah he was asked whether he had ever had malarial fever. Answering in the affirmative he was put upon large doses of quinine. His temperature soon came down and no further unfavourable symptoms occurred.

10. One of the greatest and most embarrassing mistakes that can be made in respect to diagnosis is the omission to procure a skiagraph in cases of doubtful injuries of the skeleton, and other instances of which we are all aware, but which we do not always bear in mind in actual practice. I must not enter upon this question now, but when diagnosis is being discussed I feel that it ought, at all events, to be pointedly mentioned.

It would be easy to follow the subject of this paper further, but neither time nor your patience will permit me to do so. I will only add a hope that the cases related may serve to remind us all that the task of arriving at a correct diagnosis is often surrounded by grave difficulties: that the

Hosted by Google

various sources of these difficulties must be kept in view: and that they can be overcome only by our being constantly on the *qui vive*; by taking a wide survey of all the possibilities of the case; by taking a full account of every symptom that is present—remembering that it is often the apparently trivial symptoms, or those which we are most apt to overlook and ignore, which are the most important—and by being careful to repeat our examination when circumstances may have become more favourable, and by revising our diagnosis, so as to make it certain that nothing is being forgotten or overlooked.

An Address:

IS IT IN THE BEST INTERESTS OF PUBLIC HEALTH AND OF PUBLIC SAFETY THAT THE PROPOSED PLAN OF SUPPLYING POORER WOMEN ONLY WITH MIDWIVES SHOULD BE OPPOSED;

AND, IF SO,

HOW ARE MIDWIVES TO BE DONE WITHOUT?

BY ROBERT REID RENTOUL, M.D. R.U.I.,

MEMBER OF THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM.

GENTLEMEN,—During the last five years very great discredit has been cast upon medical practitioners owing to the action of a few practitioners, who contend that the wives of the poorer and wage-paid classes should have no one to help them during their confinements but midwives. I refer to the four Midwives' Registration Bills. The first Bill was introduced into the House of Commons in February, 1890, by Mr. H. Fell Pease, M.P., who is now dead. Clause 5 of that Bill was so degrading in its proposals that I shall quote it. It proposed to enact as follows: "A person registered under this Act shall be entitled to practise midwifery in any part of England or Wales for gain, and from and after the first day of January, 1891, a person shall not be entitled to recover any fee or charge in any court for the performance of any midwifery operation or for any midwifery attendance or advice unless she be registered under this Act." This clause proposed to hand over all confinements—natural and abnormal—to the sole control of the midwife, and also attempted to empower her to perform "any midwifery operation" and to give "advice." Had it passed it would also have debarred medical practitioners from practising midwifery. Fortunately for the public safety this Bill was "talked out" in the House of Commons on its coming up for its second reading by Mr. J. R. Kelly, Mr. Brunner, Mr. Bradlaugh, and Dr. Tanner. When the gross proposals of this Bill had been pointed out its promoters introduced other Bills; in these they tried to limit the midwife to conducting "natural labours" only. But as they persistently refused to define the term "natural labour," or to provide any punishment for those who conducted labours other than natural these Bills were also vigorously opposed. All practical practitioners know that no labour can be definitely defined as "natural" until some hours or days after the labour is over; and, further, that no right-minded jury would fine or imprison any midwife whose sole offence was that she had saved the life of a mother and infant by performing some obstetric operation. In other words, they would refuse to place a penalty upon the saving of a life. I trust so would any practitioner. This proposal to supply the poorer classes with an inferior order of midwifery practitioners is retrograde, death-dealing, and injurious to health and crime-producing.

First, it is retrograde because it proposes we should revert to that death-dealing state of affairs which existed before and after 1858. You will remember that by the Medical Act, 1858, three separate classes of practitioners were recognised by Statute—(1) those educated and licensed to practise midwifery only; (2) those licensed to practise medicine only; and (3) those licensed to practise surgery only. Now I need not, when addressing an educated audience, state that to practise midwifery with the greatest protection and benefit to the public the practitioner so practising must not only be thoroughly educated in midwifery, but also in medicine and surgery. This is a truism. You will also agree that if you are called in to treat a pregnant woman or one recently confined, who is suffering from some fever or some disease of the heart, lungs, kidneys, or other organ of the body, you are a danger to that woman's life and health if you are educated in midwifery only, and not also in medicine and surgery. This great fact is due to the universal law that disease will recognise no boundary, and the affection which to-day is purely "medical" may to-morrow become a surgical complaint. The various puerperal maladies have a fearfully high death-rate, while the various midwifery operations require surgical skill of the highest kind, good nerve, and a quick perception. Some surgeons affect to smile at obstetric operations; chiefly owing to their ignorance. True, obstetric operations have often to be performed at a moment's notice and unattended by a demonstration of assistants and nurses and without much of the preliminary parade.

From these facts you will see that this threat to supply the poor with midwifery practitioners only partly trained in midwifery, and wholly untrained in medicine and surgery, is a distinctly retrograde proposal. The uneducated practitioner was denounced as a public danger by the Royal Commissioners on the Medical Acts of 1882 when they reported as follows: "Another grave defect of the licensing system lies in the fact that nearly all the medical corporations grant diplomas in medicine alone or in surgery alone. There is no point of medical reform on which there is so general an agreement as that the holding of a Licence ought to imply the possession of a complete qualification for practice—that is to say, the attainment of a sufficient standard in all the three essential branches of medical practice—medicine, surgery, and midwifery. It is our opinion that the holding of a Licence ought to be conclusive evidence of sufficient proficiency in medicine, surgery, and midwifery." Also, when in 1877 the Royal College of Surgeons of England reported to the General Medical Council regarding "women candidates for Licences in Midwifery" they did so in the following important words: "As regards any revival of the old system, whether it were for male or for female candidates, the President and Vice-President would report to the Council that in their opinion the objections to such a course are insuperable—not referring exclusively to the difficulty in which the College has been placed by the retirement of the examining physicians of its Board; but, looking also to its public interest in this matter, the President and Vice-President would remind the Council that the registrability of midwifery licences independently of qualifications to practise medicine and surgery has been brought under the notice of Her Majesty's Government by the General Medical Council as a serious error in the Medical Act ..... calculated to be injurious to the public interest, and an error which should be corrected by legislation." I need only add that this error has been corrected by the Medical Act, 1886, which provides that if any person wish to lawfully practise any part or branch of midwifery, or of medicine, or of surgery, such person must be fully educated in all these three subjects, although he practise only one of them. Yet, because a few practitioners connected with a small self-constituted and voluntary body—a subscription of 21*s.* being the sole necessity—known to its members only as the London Obstetrical Society, and having no more status than any one of the hundreds of medical societies throughout the country, have sold over £1300 worth of unauthorised "diplomas" to midwives, and this, too, in direct opposition to the requirements of the Medical Act, 1886, we have been asked to allow this society to make legal its illegal conduct and to support a Midwives Bill. Is it little wonder that with such a degrading example we should lately have had some herbalists establishing a "General Council of Safe Medicine" and selling "diplomas"? Fortunately in 1876, owing to the resolute action of Dr. Robert Barnes, the Royal College of Surgeons

Hosted by Google

of England ceased to grant their single qualification in midwifery. But when this College did so—to the deep disgrace of the practitioners forming the Obstetrical Society, be it recorded—this society took upon itself to take up the cast-off clothes of the College and to grant these single midwifery diplomas—a downgrade example which, I rejoice to say, neither the Irish nor the Scottish Obstetrical Societies have followed.

Secondly, the proposal to establish a partially trained class of midwifery practitioners for the poor only is death-dealing and injurious to the public health. If the proposal were not so very serious it would be amusing to read some of the remarks made regarding the supposed triviality of a confinement. Fortunately, statistics throw a deep and serious cast over their contention. During 1893 the deaths of 569,958 persons were registered in England and Wales. Of this number at least 5950 deaths were due to puerperal fever and the accidents of childbirth. From this it follows that 1 death in every 95 of the total deaths registered was due to a confinement—to an act which some evidently extremely ignorant persons are pleased to term "quite a natural occurrence." From statistics which I have collected from the annual reports of the Registrar-General of births and deaths I find that from 1871 to 1893 the appalling number of 48,375 women died from puerperal fever and 50,211 from the accidents of childbirth; or a total of 98,586 women, all in the prime of life. Now, if these fearful statistics related to deaths in mines or some other industrial callings, we should have questions asked in Parliament and a Select Committee at once appointed to inquire into the causes which bring about so great a loss of young lives. But woman and her offspring would appear to be a glut in the market and so they are left to perish; while others, refusing to needlessly sacrifice their lives, refuse to have any children. Unfortunately, the above high death-rate falls far short of the actual number of maternal deaths. McClintock said that one-fourth of the deaths of women after confinement were not recorded. Newsholme in his work upon "Vital Statistics" makes similar statements; while the Registrar-General in his fiftieth annual report says, "At the same time, it must be admitted that child-birth mortality is, in all probability, very much understated in our official returns." This is largely due to the fact that practitioners refuse to carry out the rule which provides that when the mother's death occurs within one month after confinement the fact should invariably be stated in the certificate of the cause of death. Some years ago Matthews Duncan startled the profession by producing statistics which proved that one woman in every fifteen died in her first confinement. This is a statement of his which has never yet been proved false; in fact, if Duncan was noted for one thing more than another it was for his love of truth. Again, if at least 5950 women died during 1893 it also follows that *every day* in England and Wales not less than 16 women lose their lives in childbed. Sixteen lives lost every twenty-four hours on an average, and this, too, in performing what some faddists—dangerous faddists—are pleased to refer to as "a perfectly natural act"! Did 16 persons lose their lives each twenty-four hours from football, bicycling, or some other "perfectly natural act," we should soon have the daily papers vigorously and persistently calling attention to this sad and needless loss of most valuable lives. You will note I do not refer to the number of women who lose their lives during pregnancy nor do I more than refer to the sick-rate and maimed-rate which follow confinements. But do not the many women whose health has been crippled in a confinement, who are physical wrecks, and who are incapacitated from attending to their household duties, show to us that the number of disasters which fall short of death after childbirth are far too numerous? Do not the large number of hospitals devoted to the treatment of women's complaints often emphasise the fact that the illness dates from the confinement? It is surely for each of us to try to lessen this great maternal death- and sick-rate following confinement. I have tried to do my small share by preventing, for so far, the passing of a Midwives Bill. I have also induced the General Medical Council, after working from 1891 to 1896, to withdraw its death-dealing and disease-producing rule, which recommended to the medical examining bodies that a student who had personally conducted only five confinements should be admitted for his final medical examination—a recommendation which Sir W. Foster described as being the subject of scoff and satire. In 1896 the General Medical Council altered this recommendation, and now each student must personally conduct at least twenty confinements before being licensed. I have further induced the General Medical Council to take up the important question of the granting of midwifery certificates which pretend to empower women to act as midwives. I have referred, for so far, to this proposal in the manner by which it would affect the life and health of women. But how does it threaten the lives and health of infants? When we think of the many causes, quite distinct from the purely obstetric, which lead to premature birth, and when we know that anyone who wishes to be able to not only detect but to treat such causes must have a very complete training in medicine as well as in midwifery, we must surely recognise the absolute necessity for the practitioner of midwifery to possess a complete knowledge of all the three branches of physic. If we fail to detect either the maternal or fœtal causes of premature birth we shall not only frequently lose many infants, but, what is still worse, we would fail to recognise and remove those medical causes which produce disease in future infants. Again, it is a recognised fact (one stated by Dr. K. Grossman) that at least 30 per cent. of the total blindness which affects persons in this country is due to infant ophthalmia. This is a disease which calls for medical training upon the part of the obstetric practitioner. I need not enlarge upon these facts to show that the practice of midwifery is most intimately bound up with our public health—that it brings us into very much closer relationship with the public than do the practice of medicine or surgery; that it is of the greatest importance from the national point of view that pregnant women and also infants shall have the very highest and not the very lowest medical skill; that in this respect National Health means National Wealth, and that it is contrary to the spirit of this country to supply the poorer people with a class of inferior midwifery practitioners—a class who would on no account be employed by the well-to-do. No doubt those few practitioners who are at the beck and call of some society ladies, or who put money in their pockets by the sale of bogus midwifery diplomas, will plausibly assert the opposite. But if it were suggested that we should register bone-setters and "medical" herbalists—the co-equals of the midwife—and empower such to treat "simple" medical and surgical patients, some would, perhaps, more readily see the gross absurdity of their proposals to register and qualify midwives to treat "simple" cases of midwifery.

Thirdly, the proposal to establish a partially trained class of midwifery practitioners for the poor only is a crime-producing proposal. When the first Midwives Bill was introduced I recognised that it would constitute a great danger if midwives were given statutory power to issue and sign certificates of the fact and cause of stillbirth or of the cause of maternal deaths. I then wrote to a number of burial boards and found that at seventy-one such cemeteries 6321 supposed stillborn children had been interred during twelve months. Sir C. Cameron, M.P., in the House of Commons called the attention of the President of the Local Government Board (Mr. Ritchie) to these figures and asked for a return. This Parliamentary return showed that during 1889 no less than 17,335 supposed stillborn children had been interred in such burial board cemeteries. No evidence is called for to show that these infants were really stillborn. In this respect it is to be remembered that it is not uncommon to bury infants as "stillborn" who have died some hours or days after birth. You are aware that one of the chief causes of stillbirth is delay in the progress of the confinement; and that if midwives are to be employed because their charges are lower than medical men it follows that midwives will refuse to increase the charge by calling in a medical man. In fact, we might make a rough rule, as follows—that the number of healthy infants stillborn will be about equal to the number of times upon which the forceps and turning should be used.

As a crime-producing factor we must also refer to the large number of illegitimate births which occur in this country, and also to the fact that the proportion of illegitimate stillborn infants is very much greater than among legitimate infants. From 1871 to 1893 no less than 1,062,618 illegitimate births were registered in England and Wales. This shows there is a very large field open for the criminal stillbirth business as well as for the abortion-monger—a business which is on the increase. Tons of abortion drugs are swallowed each year by married and unmarried pregnant women, while the daily and "religious" papers—to the

Hosted by Google

disgrace of their proprietors be it said—teem with cures "guaranteed to remove all obstructions." No practitioner of any number of years' standing fails to be requested by some man or woman to kill the infant in the womb, while the number of women, mostly midwives, who keep certain "herb shops" is greatly upon the increase. When we consider these grave facts; when we remember how readily a life may be taken without the danger of this being detected; when we know that only those present at a birth can tell whether the infant was or was not legally born alive, we can recognise the great truth which is contained in the statement of Dr. R. Barnes in his letter to the *Times* upon this question when he said: "There is no department of medical practice in which so many moral, social, legal, and criminal complications arise as in midwifery." Are we, therefore, to hand over this great and important branch of the practice of physic to semi-educated persons, whose poverty, if not their will, would press them to perform illegal operations? Is the Medical Act of 1886 to be repealed at the bidding of a number of faddists, and is the practice of midwifery to be divorced from that of medicine and surgery? In the interests of the public health, in the interests of women and children, and in the interests of a profession which must have a real practical education and which must not be steeped in poverty, if it is to keep its place among moral and learned bodies, I have contended, and shall continue to contend, that midwifery, medicine, and surgery are a sacred trinity which must not be dissolved.

Sir J. Paget has shown, in his address to the International Health Congress in 1884, that the people of this country, and within the ages of fifteen and sixty-five years, lose at least 20,000,000 of weeks' work each year owing to sickness, and that this, calculated at £1 per week, means a loss of £20,000,000 each year. A very great amount is lost through sickness and death of confined women and of infants—a fact which is shown by the premiums placed upon married women's lives by insurance companies and by the inability of a large number of friendly societies to admit women.

In October, 1896, Sir W. Priestley, M.P., when delivering the winter opening address to the students of the Liverpool University College, made some very glaring remarks upon the number of women attended by midwives, the number of midwives, and the maternal death rate. First, he said there were from 10,000 to 15,000 midwives in England and Wales. This is far from the fact, because the 1881 census shows that there were only 2800 midwives! It does seem unaccountable that the supporters of midwives' registration cannot agree among themselves as to the actual number of midwives, because only a few weeks after his address (Nov. 11th, 1896) Miss C. Ellis read an address before a Leicester meeting of the Women's Liberal Association, when she stated there were only 4500 midwives in England and Wales, and that these conducted 450,000 confinements each year, no less than 3000 of whom died each year! Thus we have the figures, 2800 4500, and Sir William Priestley's 15,000! Who is right? Secondly, Sir William Priestley said that midwives attended 500,000 confinements each year. Let us look into this very startling assertion. During 1894 there were 890,289 births registered in England and Wales. In the same year there were 21,055 registered practitioners practising in England and Wales; therefore, according to Sir William Priestley, each practitioner conducted on an average only eighteen confinements each year, or a little over one per month. Any established practitioner can at once detect the absurdity of his mythical assertion. Again, if midwives conduct 500,000 confinements each year this gives each midwife a maximum on an average of thirty-three confinements each year, or only about three each month. From these latter figures we can further deduct the most instructive fact that a midwife with about three confinements each month, and obtaining a fee of 10*s.* for each, or 30*s.* a month, could not make a fair and honest livelihood among the poorer classes alone—she would have to act among the well-to-do. Thirdly, Sir William Priestley gravely asserted that women delivered in hospitals are much safer and less exposed to danger than those delivered in their own homes.

Unfortunately, I had, when giving evidence before the Select Committee of the House of Commons, to show how sadly unreliable and wide of the truth these hospital statistics are. I pointed out that in most lying-in hospitals (*a*) all unmarried women are rigidly excluded, thus keeping out the illegitimate class, who have an exceptionally high death-rate; (*b*) that in others, those women pregnant for the first time are excluded, thus shutting out those who give the highest death-rate of all—1 in 15; (*c*) that women who had no child living were refused help, thus excluding those malformed or who had some maternal disease which had caused the infant's death; (*d*) that a large number of women leave the lying-in hospital within from seven to ten days after confinement, and are afterwards lost reckoning of; (*e*) that confined women attacked with fever, &c., are removed from the lying-in to a medical or surgical ward or to a fever hospital and are thus lost sight of; (*f*) that the rule of the Registrar-General is frequently ignored which requires that when a woman dies within thirty days after her confinement this fact should be stated in the certificate of the cause of death; and (*g*) that when lying-in hospitals have a low death-rate this is due altogether to the fact that medical practitioners are called in to assist by operation, &c. It is a great pity when Sir William Priestley lends himself to the circulation of any statistics which cannot bear one moment's honest criticism. Medical and surgical statistics are frequently scoffed at, and I think any practitioner who lays his profession open to public contempt should be severely dealt with. Every intelligent practitioner knows that we have more than sufficient practitioners with their assistants and students to conduct all the confinements in this country. In 1883, there were, on an average, 57 births to each practitioner; in 1893, 44; and in 1894 only 42 to each practitioner, or not one per week. Moreover, the birth-rate is steadily falling each year. It is decreasing, while the number of practitioners is increasing—or as the General Medical Council in their Fourth Statistical Report, 1886, states:—"The net increase of the profession in England during the quinquennium ..... was not less than 826 beyond what was requisite to keep pace with the population, showing an annual excess above average requirements of more than 150."

It is quite evident, therefore, that Sir William Priestley has been misled by being supplied with very fallacious statistics. Not only do the above figures show this, but I may further mention that in 1895 the Honorary Secretary of the "Affiliated Benefit Nursing Association" sent a circular letter to sixty-two districts situated in agricultural localities in many counties. The replies from the local secretaries showed that 779 women had been confined, and that of this total, 629 women had engaged a medical practitioner for their confinement; 29 sent for a practitioner not previously engaged; 32 were managed by a cottage nurse alone; while only 26 had a midwife. Do these figures bear out Sir William's wonderful statistics? Perhaps he is not altogether an impartial authority, because, not only was he chairman of a small committee of the Royal College of Physicians of London which reported to the Medical Council in favour of the registration of midwives (this being fortunately neutralised by the statesman-like report from the Royal College of Physicians of Ireland against registration), but because in his address above referred to he says: "The medical profession should be on its guard against agitators, whether it be on medical defence, midwives bills, or direct representation of the profession." Further, when in 1876 Dr. R. Barnes refused to continue to act as an examiner at the Royal College of Surgeons of England in the granting of the single licence in midwifery his co-examiners, Sir William Priestley and Dr. A. Farr, were also pressed to resign. Why, therefore, does Sir William Priestley place himself in this ambiguous position of having refused to grant licences in midwifery at the College, while, on the other hand, he insists upon backing up a few practitioners outside the College who privately grant these licences in midwifery? Is consistency neither a virtue nor a necessity among us all? Surely any practitioner, even one who has never been known to hand over one of his well-to-do patients to a midwife, must recognise that this country's and her colonies' success depend very largely upon population and that, if it be necessary, the public rates must pay for proper attention to pregnant women of the wage-paid and poorer classes, just as now fever and workhouse hospitals are supported by rate aid. If half of the total women confined (445,144) are unable to pay £1 each for a medical practitioner during their their confinements, this would mean a public rate of only 1*s.* 6*d.* per annum upon each head of a family in England and Wales.

I shall next discuss the question—Is it in the best interests of the public health, and of the public safety that the proposed plan of supplying poorer women with midwives, should be opposed; and if so, how can midwives be done without? I am strongly of opinion that the poorer classes can do without midwives. I have shown that the public health and

Hosted by Google

the public safety would be improved if every woman in her confinements were provided with a medical practitioner and a common-sense nurse. Long ago midwives, bone-setters, and medical herbalists may perhaps have had their uses, but now there is ample provision for all pregnant women of the poorer classes, by means of the Poor-law medical service, lying-in hospitals, maternity clubs, and provident dispensaries, and practitioners who accept small fees varying from 4*s.* to 15*s.* I shall refer in some detail to those means by which every pregnant woman belonging to the poor and to the wage-paid classes can now, with the greatest facility, secure the services of a medical practitioner and a practical nurse during her confinement. These conditions being in existence there will be no necessity to describe vague proposals.

I. *The Poor-law Medical Service.*—Articles 182 and 183 of the order of the Poor-law Commissioners of July 24th, 1847, are as follows (they refer to the subject of extra fees for attendance upon midwifery poor-law patients): "The cases in which any medical officer, either for the workhouse or a district, shall be called on by order of a person legally qualified to make such order to attend any woman in, or immediately after, childbirth, or shall under circumstances of difficulty or danger without any order visit any such woman actually receiving relief or whom the guardians may subsequently decide to have been in a destitute condition, such medical officer shall be paid for his attendance and medicine by a sum of not less than 10*s* or more than 20*s.*, according as the guardians agree with such officer." "Provided that in any special case, in which great difficulty may have occurred in the delivery or long subsequent attendance in respect of some puerperal malady or affection may have been requisite, any district medical officer shall receive the sum of 40*s.*" This humane order (a copy of which may be obtained from the Local Government Board, London) is in full force in many unions of England and Wales; it does not apply to Ireland or Scotland. In some unions, such as Liverpool, the medical officers have been "contracted out" of this order by the guardians, although such action by the guardians is distinctly illegal. I regret that any practitioner should be so destitute of common sense as to sign such a contract. Why should he lower a public and life-saving order as this to a purely personal item? I think before doing so he should have considered those who come after him and of the evil results likely to follow when other guardians adopt his standard for their guidance. Before doing so such practitioners should have called their local brethren together in council and asked them for their advice. Instead of this existing rights have been betrayed and surrendered, an evil precedent has been established—an illegal precedent which, I would suggest to those who have made it, should at once be set aside by their giving notice to the guardians (having first obtained the support of the local profession) that after a fixed date they will not be bound by it. I am glad to say that I know of guardians who pay not only their district but their workhouse medical officer the fee of 20*s.* for conducting a natural labour and not the minimum fee of 10*s.* I have been told that some medical officers abuse this order by using instruments too often so as to secure the fee of 20*s.* This is one of those vague charges which any uneducated person can make and without the slightest proof. It has been suggested to me that a uniform fee of 20*s.* should be paid for each confinement, whether natural or abnormal. I would urge, on the other hand, that the fee should be uniform for all kinds of labour and that such fee should be 40*s.* I am fully convinced that if Poor-law medical officers will exert themselves the Poor-law medical service can be made the supreme medical service in this country. The days when it was preached, and unfortunately practised, that it was a disgrace for any poor woman out of work to ask for help from the Poor-law in her time of trouble and trial are, thank God, gone, and gone for ever. Our Poor-laws, especially as they affect the sick poor, are becoming more humane and more sympathetic each year. Thinking men are recognising the fact that this question of looking after the poorer women during confinement is of national and not of purely personal importance. Our fleet must be manned, our army must be recruited, our colonies must be populated, and the loss through death more than made up. There is therefore a national reason, and it is one which has received but scant attention, why we should take extreme care of what some unthinking persons term the "surplus population" and the "residuum."

The various reports lately published relating to the sick poor have done much good. By the Medical Relief Disqualification Act, 1885, it is enacted that—"When any person in the United Kingdom receives for himself or for any member of his family any medical or surgical assistance or any medicine at the expense of any poor-rate" such person shall not be deprived of his municipal or Parliamentary vote. Section 4 of this Act defines what is meant by "medical assistance" or "surgical assistance." As it does not specifically mention the words "obstetric assistance" I communicated with the Local Government Board and asked if the Board would hold that these words included "obstetric assistance." Under date of Jan. 10th, 1896, the Board replied as follows: "It seems to the Board that the attendance of a medical practitioner in cases of midwifery at the cost of the poor-rate may properly be considered medical attendance within the meaning of the Medical Relief Disqualification Act, 1885." Does it not seem strange that a British Parliament up to 1886 considered it a crime, punishable with disfranchisement, for a working man to suffer from an illness which by placing him out of work compelled him to ask for Poor-law medical relief for himself or his wife? Many have no idea of the large number of women confined under the Poor-law medical service. Sir F. Mouatt, late Local Government Board inspector, in 1881 delivered an address in which he showed that during the ten years 1871 to 1880, no less than 87,726 women were confined in 644 workhouses in England and Wales. These figures do not include those confined outside the workhouse but under the district Poor-law medical officers; therefore on an average 8772 confinements occurred in the workhouses each year, and these calculated at £1 each would cost the poor-rate only £8772 per annum in fees to their medical officers—8772 infants for so small an expenditure! I am at present engaged in trying to induce some member of Parliament to move for a return showing the total number of Poor-law confinements, &c., which occurred last year in the United Kingdom. I think the above facts go to prove that with the existing arrangements of our Poor-law medical service, and without establishing any partially educated midwifery practitioners, we have now the means by which all poor pregnant women can be supplied with fully-educated medical practitioners.

But it may justly be asked, How are these poor women to be nursed? The present in-door Poor-law patients have nurses. In connexion with those confinements which occur in the district Poor-law service I would earnestly call your attention to the General Order of the Local Government Board, Jan. 27th, 1892 (No. 26,978), which relates to the appointing of district nurses by boards of guardians. This order is of the greatest practical importance and I shall quote its chief provisions. (Copies may be obtained from the Local Government Board, London.) Article 1.—"The guardians of the poor of any union or separate parish in England or Wales may, from time to time, as they think fit, with our approval, appoint one or more persons to act as nurse or nurses to the sick poor relieved by the guardians out of any workhouse, such persons to be termed district nurses.' Article 4.—"The duties to be performed by a district nurse shall be: (1) To attend duly and punctually as a nurse upon any poor person or persons in receipt of medical relief when directed by the guardians or upon receipt of a written or printed order from any relieving officer, in any case in which such officer may be authorised by regulations to be prescribed by the guardians to give such order; (2) to obey any directions of the district medical officer in attendance upon any poor person in regard to the nursing and treatment of such poor person." Article 5—"No district nurse shall undertake the duties of a midwife." This order has been sent by the Local Government Board to each board of guardians in England and Wales. I regret to find that it has not been discussed by all medico-ethical societies and that Poor-law medical officers have failed to request the guardians to put it into force. Some guardians, I am told, instead of appointing such nurses subscribe a stated sum to nursing associations in order to obtain the services of their nurses.

Does it not seem strange that all guardians do not put these two life-saving and health-saving orders of 1847 and 1892 into active operation? I think it is the duty of each medico-ethical society to take such important subjects up, to go as a deputation to their board of guardians with the view of inducing them to adopt these two orders, and, further, to see that a number of their members are elected as guardians. No doubt some guardians, caring more for the

Hosted by Google

Poor-rate than for the health of the poor whom they are appointed to "guard," opposed these two orders. This was the case at Leicester, when in 1895 the guardians there appointed a midwife to the place and to perform the duties of their district medical officer in confinement cases. Fortunately, the Local Government Board must confirm or reject the appointment of such persons. The result is that the following important letter was sent to the Leicester guardians:—

"Local Government Board,
"Whitehall, S.W., April 15th, 1895.

"SIR,—I am directed by the Local Government Board to advert to your letter of the Feb. 28th informing them of the appointment of Miss Masters, a fully trained certificated midwife, to devote the whole of her time to the parish midwifery cases in the Leicester Union, at a salary of £65 per annum. The Board, having given the subject their careful consideration, direct me to state that they can only recognise Miss Masters as a midwifery nurse on the understanding that she must in all cases act under the direction and supervision of the medical officer, who must still be held responsible for all cases and who must visit the cases himself.

"I am, Sir, your obedient servant,
"W. E. KNOLLYS, Assist. Sec.

"T. Mansfield, Esq., Clerk to the Guardians of the Leicester Union, Leicester."

The result of this letter now is that the guardians have been compelled to do their duty to poor pregnant women. Naturally, the Local Government Board recognise a time might come when some low-class practitioners would start selling diplomas in medicine and surgery as well as in midwifery, and that some guardians might, in their desire for rotten cheapness, appoint bone-setters and herbalists to look after the sick poor when suffering from surgical and medical illnesses.

Following the example of Leicester, the Peterborough guardians on Nov. 12th, 1895, adopted the following resolution and sent it to all the guardians in England and Wales asking them to adopt it. It is as follows: "That the members of the board are of opinion that it is desirable that boards of guardians should have the discretionary power of appointing duly qualified midwives for attendance at childbirth in place of the district medical officer, subject to the condition as laid down in the Poor-law Board's official circular No. 88." I may mention that there is no such circular. However, the wording of the resolution shows the real meaning of the midwives' agitation—to dismiss medical officers and to place midwives in their stead. It is evident that these incapable Leicester and Peterborough guardians of the poor, prompted by a few society ladies who have been attempting to foist a so-called Midwives Bill upon Parliament, attempted to do an illegal act and one most unworthy of their official position. To their evil influence we may truly attribute the action of the committee of the Liverpool lying-in hospital, which dismissed their visiting medical staff and appointed a midwife to take their place—an action which, I am glad to say, the practitioners of Liverpool, led by Dr. W. M. Banks, resented with such contempt that the busybodies forming this committee gave up the fight and reinstated the staff. An action such as this shows that we must always depend upon local effort only, and that we must not look to central bodies in London. Decentralisation is the order of to-day, and local effort alone can bring success.

In connexion with the great powers which guardians possess of supplying not only obstetric, but also medical and surgical treatment to the poor, I shall digress for a few minutes so as to call your attention to a most interesting action taken lately by the Whitechapel Board of Guardians, London. It was found in that union that some poor people in sudden illness died before an order from the relieving officer could be obtained. Therefore these guardians wisely sent the following letter to all medical practitioners resident in their union:—

"DEAR SIR,—I am directed by the board of guardians to state that, in the event of your being called to a case of urgent sickness of a destitute person within the area of the Whitechapel Union, under the circumstances of the attendance of the district medical officer not being immediately available, they will be prepared to pay you a fee for one visit and medicine, according to the following scale, upon condition that notice is given to me by post or otherwise within twenty-four hours of the time of such visit. Scale of fees: From 10 P.M. to 8 A.M., 7s. 6d.; from 8 A.M. to 10 P.M., 3s. 6d. The present arrangement being experimental I am to add that it will extend only to the 31st of December.—Yours faithfully,

"July, 1895." "W. VALLANCE, Clerk.

I consider this a good plan for supplying destitute persons in urgent sickness with one visit and medicines. It resembles the "Night Medical Service of Paris," a full description of which will be found in my book, "The Reform of our Voluntary Medical Charities." Mr. Vallance informs me that he leaves it absolutely to the practitioner called in to decide whether the patient is actually "urgent" and "destitute." I hope each medico-ethical society will bring this plan before their guardians of the poor, with the view of inducing them to adopt it, if only for a few years' trial. The Whitechapel guardians, in order to be thoroughly certain of their position, asked the Local Government Board for their advice, when the Board replied as follows:—

"Local Government Board, Whitehall, London, June 6th, 1895.

"SIR,—I am directed by the Local Government Board to advert to your letter of the 13th ultimo, and in reply to your inquiry upon the subject of medical attendance in urgent cases of sickness, &c., among the poor, to state that the guardians are empowered, by Section 2 of the 11th and 12th Vict., Chap. 100, to pay for any medical assistance rendered to any poor person, by reason of any accident, bodily casualty, or sudden illness, although no order shall have been given by them or their officers or overseers; and the Board considers that it would be lawful for the guardians to inform medical practitioners in the union that they would be prepared to make payments under the powers so given to them in cases coming within the terms of the Section above referred to, stating at the same time the amounts which they would be ready to pay for such assistance.—I am, &c.,

"W. E. KNOLLYS, Assistant Secretary.

"W. Vallance, Esq., Clerk to the Whitechapel Board of Guardians."

Another improvement which might be effected in medical Poor-law administration is that to which Mr. Colin Campbell has called my attention in his union—that of Saddleworth, Yorks. They have adopted an enlightened system; in it all the medical practitioners resident therein may be appointed Poor-law district medical officers. At present four local practitioners act as such. Their appointment is made by the guardians and submitted for confirmation to the Local Government Board. The patient, on obtaining an order from the relieving officer, selects whatever practitioner he or she wishes. Each order carries a payment of a fee of 7s. for each case of illness, no matter whether it be for extracting a tooth or for treating a case of pneumonia. A "case" of illness is defined as one which does not last for more than three months; if it does, then another 7s. is paid to the medical officer. Mr. C. Campbell states that the advantages of such a plan are to the poor very marked. I therefore hope each medico-ethical society will bring this plan before its local board of guardians. By the Act of George III., Chap. 59, 1819, and by the Poor-law Act, 1834, guardians are empowered to grant relief on loan to the poor and to attach their wages in repayment. In this way the guardians can check abuse and at the same time help the genuine poor.

If guardians and Poor-law medical officers will adopt the above suggestions, and if we can have Poor-law infirmaries opened for the clinical instruction of senior students in practical obstetrics, &c., nothing but good will result. By Section 29 of the Metropolitan Poor Act, 1867, it was provided that students could be so educated. Unfortunately, this section was repealed by Section 20 of the Metropolitan Poor Amendment Act, 1869. Neither, however, apply to the provinces. Since 1886 the Cork Union Infirmary with its 1200 beds has been opened to students. In 1888 the Select Committee of the House of Lords upon Poor-law relief strongly urged the opening of these infirmaries, while the Select Committee of the Lords upon Metropolitan Hospitals in 1892 reported similarly. By the Poor-law Act, 1889, Section 4, the London fever hospitals under the Metropolitan Asylums Board may be used for the education of students, while the Galway Hospitals Act, 1892, makes similar provision. If to this it were provided that the visiting medical staff of the workhouse infirmaries were made to include several practitioners the inmates would benefit.

At the Birmingham Workhouse Infirmary there is one visiting physician and one surgeon, one senior and two junior assistant resident medical and surgical officers, and one resident clinical clerk. I feel I have proved that by a proper working of our poor-law, by means of *(a)* each board of guardians adopting the extra midwifery fee order; *(b)* by adopting the order relating to the appointing of district nurses; *(c)* by appointing all the practitioners established within the union as district medical officers; *(d)* by their paying a fee of seven shillings opposite each case of illness; *(e)* by adopting the scheme of the Whitechapel guardians relative to the payment of one fee to any practitioner for a visit to an urgent and destitute case of illness; *(f)* by opening the Poor-law infirmaries for the education of students; and *(g)* by appointing a large staff of visiting practitioners to the infirmary, we now possess the means, and the very ample means, of supplying every poor pregnant woman in this country with an efficient medical practitioner and practical nurses.

II.—I shall next refer to the second method by which the

Hosted by Google

poorer classes of pregnant women can obtain efficient medical aid without midwives. I refer to the voluntary medical charities. In 1891 I found that 51,049 women received aid from such charities in the United Kingdom. I would suggest that the system in force at the Newcastle and Oxford lying-in hospitals be adopted by all lying-in hospitals and dispensaries. At Newcastle they have ceased to employ midwives. The town is divided into two districts, a practitioner being appointed to each. Each practitioner is paid £40 per annum and also 10*s.* 6*d.* for each confinement conducted by him. At Oxford each of the two practitioners is paid £70 per annum and also 10*s.* for each confinement conducted. A district nurse is also appointed to nurse the women. Now, if every lying-in hospital had such paid medical officers and nurses; if each practitioner in the neighbourhood formed one of the staff; if each poor pregnant woman were permitted to select whatever practitioner she wishes; and if each medical officer had a senior medical student as his apprentice—one who had passed his preliminary and first and second professional examinations and who had completed his dissections and post-mortem classes—great good would follow to all concerned.

III.—The third system, which now allows the poorer classes to do without midwives, is by using and developing maternity clubs and provident dispensaries for the benefit of those women who are willing to pay a part of the medical fee. In London there is the St. Barnabas and St. Paul Maternity Club, managed by a few ladies. The patient pays 10*s.* and the club committee 10*s.*, the practitioner receiving the 20*s.* A similar club exists in Burnley. In Liverpool the parson of a church has established a maternity club. The patient sends for the midwifery nurse and the latter sends for the club's medical man, who stays if necessary with the patient. The vicar has adopted an excellent plan for obtaining the salary of the medical man. In the English Church a mother after confinement is "churched," and she pays a fee for this varying from 12*s.* 6*d.* downward. The vicar uses such fees to pay the medical man. The patient pays 10*s.*, this being collected by the sisters of the church and not by the medical man. The latter is paid a fixed salary provided the confinements do not exceed a fixed number. Now if practitioners will present such an illustration to their local clergy, and if their wives will only take the trouble to explain this to their ladies' meetings, I feel sure maternity clubs will—if reserved for the deserving poor who can and will help themselves—continue to increase.

I need not do more than call your attention to the means offered by well-conducted provident dispensaries. By means of these a woman can, by paying about sixpence per week during her nine months of pregnancy, secure the services of a practitioner. In June, 1887,[1] I compiled a table in which I gave statistics of eighty-eight provident dispensaries. I would also refer you to the Hearts of Oak and the Royal Standard Friendly Societies which provide for the payment of a lump sum, varying from 30*s.* to 40*s.*, to their club member when his wife is confined.

In connexion with this scheme a most important question remains to be answered. I refer to the supplying of pregnant women with good, sensible, and practical nurses. The "trained" hospital nurse, with her high charges and much higher notions, is not in any way suited to the requirements of the wives of the artisan, agricultural, and wage-paid classes—that is, the larger portion of the people of this country. In April, 1896, Sir D. Duckworth, when writing to Dr. W. Banks, said: "In truth, it is a very serious matter, and it rests with us to put a stop to this absurd movement. Nurses are now taught far too much and are ceasing to be of the use they are intended for. Nurses are now taught a smattering of medicine and much else that unfits them to do the plain duties of a nurse. I have good reason to know all that is in the air just now *re* women in relation to all parts of our profession, and I feel sure we must make a firm stand at once and stop this cant and nonsense that is so prevalent." For my part I can never understand the action of those practitioners who lecture nurses upon uncalled-for subjects and who put nonsense into their heads, unless it be done in the hope that such nurses will act as touting agents for these young lecturers who seem to have little else to do than "deliver" lectures. This absurd conduct is only on a par with that of those who lecture to policemen, "medical" herbalists, and others on surgery, and then bestow "diplomas" upon which it is prominently stated that the person named is "qualified to render first-aid," no matter evidently whether a practitioner be present or near at hand; and at a time too when the Commissioner of the London police has issued an Order authorising the payment of a fee of from 7*s.* 6*d.* to 3*s.* 6*d.* to any practitioner called upon by the police to an accident or case of sudden illness. If the above description of medical or surgical nurses be true it is more than true of those midwives who are also supposed to act as monthly nurses. The ordinary midwife does not act as a nurse or live with the confined woman. She tries to act just as like a medical practitioner as possible; she pays a few visits for five or seven days, and, perhaps, washes the mother and infant, but as to making herself useful in the house, cooking the patient's food and that of the husband and children, or actually nursing the mother and infant, she scorns the idea—in fact, she requires a nurse or maid to look after her. In order to neutralise the great blanks of the present nursing arrangements the "Holt-Ockley" system of nursing has been established. Its full title is "The Benefit Association for Providing Nurses for the Sick in Country Parishes," and its central office is at 12, Buckingham Palace-road, London. It was founded in 1883, and in 1896 there were 89 societies of this type in England, these supplying 379 parishes with 280 nurses. It is based upon the provident or insurance system, each person paying during both health and sickness. The people of a parish or group of parishes in which a branch is established are divided into four classes, viz.: (1) labourers who pay an annual subscription of 2*s.*; (2) artisans and servants who pay 3*s.*; (3) farmers and tradespeople who pay 5*s.*; and (4) gentry who pay 10*s.* When a nurse is required, a weekly fee of the same amount is charged—i.e., 2*s.*, 3*s.*, 5*s.*, and 10*s.*, according to the class. These charges are very moderate. Rule 14 shows the practical nature of the system:—"When attending a cottager's wife, the nurse will be expected to do all that is required for the care of her patient's family, with the exception of the washing." Miss B. Broadwood, hon. sec. and founder, writes to me as follows:—"Our great object is to enable cottage women to afford good nursing in addition to the services of a medical man and we are continually encouraged by finding that everywhere these women keep a cottage nurse until the baby is a fortnight old and that consequently they make really good recoveries." Nurses are supplied to patients who reside within two miles of the nurse's residence, and her journey to and from the patient is paid by the patient. The patient also provides board and lodging for the nurse. A nurse is paid a fixed salary of from £26 to £30 per annum. In confinement cases double charges are made if no practitioner is engaged. Each local committee of ladies agrees to collect £8 per annum opposite each parish included in the local branch and an additional £1 for every 100 persons in the district over 800. If such Holt-Ockley nursing societies were put into force in connexion with maternity clubs and provident dispensaries a very fine system would be provided for a very large portion of the wage-paid classes. To obtain a good nurse for 9*s.* for two weeks is only fair exchange. And here I would say, Does it not seem strange that people will willingly expend much more money for seeing an infant out of this world than they will for helping it to enter, just as many husbands will spend £10 in burying a wife to whom he has refused 20*s.* to help her in her confinement? It is a sad reflection upon the besotted condition of some men's minds.

IV.—The fourth and last system which allows the public to do without midwives is that large number of practitioners who conduct a confinement for a fee varying from 4*s.* to 15*s.* Do not think that there is but a small class of practitioners who are now compelled, owing to the competition with medical charities, medical aid associations, and midwives, to accept so small fees. In my own practice 30*s.* is my lowest confinement fee, but I find that when I have to visit the patient and her infant for about two weeks my average fee for the confinement is about 3*s.* 6*d.*, the remainder being placed opposite the visits. But how degrading must the inference be when some obtain a fee of from 4*s.* to 5*s.* 3*d.* for both confinement, visits, and vaccination included.

I hope my address proves completely that it is in the highest interests of the public health and public safety that the suggested supplying of the poor and the wives of the

[1] Brit. Med. Jour., June 18th, 1887.

Hosted by Google

working classes with midwives, whom we would never dream of employing for our own wives or for the well-to-do, should be dropped. The poor and the wage-paid classes are already more than amply provided for. Let medico-ethical societies and others interested see that the existing powers are put into force and honestly administered. Our duty as medical practitioners to the public, to pregnant women, and to infants in this great obstetric question is truly enormous. The fact that, with our parrot-like garrulity and boasting of the results of "antiseptic midwifery," the number of women who die now is, even with "cooked" statistics, very little less than the number who died years ago, should appeal to us, not only as men but as obstetric practitioners, and should make us shun those who would divorce the study and practice of obstetrics from that of medicine and midwifery. Such persons would have us return to those death-dealing days when pregnant women were not given the benefit of educated practitioners. In 1827 the Royal College of Physicians of London described midwifery as "an act foreign to the habits of gentlemen of enlarged academic education," while later it had actually the effrontery to refuse its highest diploma to those who dared to practise midwifery. These are the predecessors of this College who in 1891 humiliated themselves by reporting to the General Medical Council in favour of midwives registration, evidently showing by their action that "the evil which men do lives after them." In 1843 even the Royal College of Surgeons of England refused their Fellowship to those who practised midwifery; while in 1733 the Royal College of Physicians of Ireland earned an historical disgrace by refusing their Fellowship to Sir Fielding Ould, a practitioner whose "base crime" was that he had been guilty of saving the lives of thousands of women and of infants. It is seldom the bright pages of medical science have been so bedaubed; but it only shows that history repeats itself when in 1896 we have a few practitioners forming a private obstetrical society and selling pseudo-diplomas to midwives, and when a few others, trying to make legal their illegality, try to smuggle a Midwives Bill through the House of Commons. To-day we are threatened with a revival of medical Pharisaic cant—the worst and most dangerous of all cant. The question is, Are we medical practitioners to range ourselves on the side of humanity and of justice to poor women; or are we, like mendicants, to be dictated to by a number of faddists, by a few society ladies who have nothing to do, and by a few self-styled "leading" practitioners who have so far forgotten themselves as to attempt to repeal the life and health-saving provisions of the Medical Act of 1886? It is for practitioners and for them alone to decide. If each practitioner when a new Midwives Bill is introduced will at once write to the Member of Parliament representing his division and ask him earnestly to oppose such Bill, this will prevent it from passing. I would ask that practitioners do not lend themselves or be parties to a revival of that atrocious cant and hypocrisy which has left a permanent stain upon the colleges, upon those supposed to be the leaders of a humane calling, and which has been the means of causing the death of an immense number of women and infants. Each year women, and especially women residing and working in cities and towns, seem to be becoming weaker and less fit to undergo the great trials of maternity and nursing their young infants. The supposed "natural" act of confinement and good recovery therefrom are becoming more "unnatural." Therefore I ask, Is it fair that under all these circumstances women should be denied a full share of all the improvements in our knowledge of obstetrics? If it be fair, then I reply to those who say so that to be consistent they should when ill not share in the advancements made in medical and surgical science, but should call in the aid of only the "medical" herbalist or bonesetter.

As the General Medical Council will be again called upon by me to deal with those who issue bogus diplomas in midwifery, &c., I wish to ask each medical society to adopt the following motion:—"At a meeting of the ....., composed of ..... members, duly convened and held at ..... on the ..... day of ....., 1897, Dr. ..... in the chair, the following motion, proposed by Dr. ....., seconded by Dr. ....., was agreed to, 'That on and after June 1st, 1897, whenever any registered medical practitioner or any practitioner entitled to be registered (other than practitioners empowered by the Medical Act, 1886), either directly or indirectly issues, or sanctions, or takes part in the issuing of, any instrument or document which professes to empower the holder of such instrument or document to practise, or ot hold themselves out as being in any way entitled to practise, any part or branch of the practice of medicine, or of surgery or of midwifery, such practitioner so doing shall, on due proof being given, be judged by the General Medical Council to have been guilty of infamous conduct in a professional respect and his name shall be erased from the Medical Register and any registerable qualification taken from him to the body or bodies which granted such.' That the secretary forward a copy of this resolution to the President of the General Medical Council, 299, Oxford-street, London, to the medical journals, to Dr. R. R. Rentoul, and the four other Direct Representatives."

If the majority of practitioners object to adopt this motion, then it must follow that as their direct representative upon the General Medical Council I must let this most vital question drop. But if they adopt this motion and send it to the General Medical Council then I can say, and say fearlessly, that I speak for and in the name of my constituents and in the interests of the public health.

CREOSOTE IN THE TREATMENT OF PLEURO-PERITONEAL TUBERCULOSIS IN CHILDREN.

BY PROFESSOR THOMA.

PERITONEAL tuberculosis in children has for several years been treated by laparotomy, and the results are often very good. We have learned, also, to distinguish the different forms of this disease, so that its diagnosis and treatment are easier than formerly. Laparotomy is no doubt the best and quickest of all methods for dealing with those cases in which the peritoneum is covered with miliary tubercles; but it is always a serious operation and one also which not every medical practitioner is competent to perform. Moreover, the parents of the little patients are usually averse to surgical interference and anxious for the employment of some other means, so that it is not surprising that physicians should welcome a non-surgical treatment of this dangerous illness. In former years general tonics, painting with collodion, and the local application of iodine were principally relied on; but the results were often bad. Ichthyol has been employed of late years; it is certainly a good remedy, and in spite of its disagreeable smell I have many times used it with satisfactory results in acute inflammations of the peritoneum. It has frequently happened, however, that these various methods were either ineffectual or else so tedious that children were obliged to stay too long in the hospitals.

Not long ago the idea occurred to me that in these cases creosote might be advantageously administered in enemata. The first writer who recommended this treatment was Dr. Revillet of Cannes, but he employed it only for the treatment of phthisis, and after him many physicians have had favourable results. Sometimes this substance disagrees with the patients, causing diarrhœa and pains in the abdomen, so that it has either to be discontinued or combined with acetum opii ("black drop"), but this adjunct does not always succeed and is often contra-indicated. Another difficulty is the necessity for the patient's retaining the enemata as long as possible, in order that the creosote may be completely absorbed. With very young children this is hardly possible, but with my two little patients it was very easy. The enema was given each evening when the child was quiet and before putting the patient to bed. At first the child could not retain the enema more than three or four hours, but after some days the child slept well and on many occasions only a little oil was found in the morning along with the first motion of the bowels. Dr. Revillet directed the enemata to be prepared with water, a small quantity of almond oil, and the yelk of one egg. Recently, however, it has been proposed by a chemist of Grenoble to administer creosote in milk; forty-three drops of creosote are mixed with a quarter of a glass of milk and water is afterwards added. This method is evidently more simple and has the advantage that the milk is taken by the mouth, for everybody knows the difficulty of feeding an unwilling child. Nevertheless I prefer the association of

Hosted by Google

cod-liver oil with creosote. In an interesting memoir presented to the Faculty of Medicine in Geneva, Dr. Loppino, confirming the experimental researches of Professor Schiff, has proved that fat is very well absorbed by the rectum, and that oleaginous injections are highly important agents in combating emaciation and cachectic states. Dr. Loppino has never seen any bad effects resulting from the practice; the best results were obtained in the case of neurasthenic and tuberculous patients, and it is a useful mode of carrying out the treatment by over-feeding introduced by Dr. Weir Mitchell. This circumstance induced me to try enemata composed of a mixture of cod-liver oil with creosote. At the outset each enema contained 150 grammes (about four ounces) of emulsified oil and 0·5 gramme (8 grains) of creosote, but after from eight to ten days I gave 1 gramme (=15½ grains) of creosote. In the first case the child took in the course of some days 1·5 grammes of creosote; diarrhœa ensued, and the enemata had to be discontinued. After the treatment has been continued for some weeks it is a good plan to suspend it for five or six days and begin again. I have not noticed that the taste of creosote was perceived by the children; their appetite was somewhat impaired at first, but it was not lost and it subsequently improved. By this method it is possible to relieve the disorders of the bowels so frequent in this illness. I think that the antiseptic action of creosote is valuable against intestinal fermentations; it is not unusual to find constipation alternate with diarrhœa in the first stage of tuberculous peritonitis, an important cause of that condition being weak digestion and the slowness or rapidity of the movements of the intestines. The antiseptic action of the mixture of cod-liver oil and creosote is very efficacious against these troubles and after some days an improvement will be seen. The absorption of the creosote was unquestionable, for on many occasions the urine was dark-coloured. It is possible that creosote may have a curative effect on tuberculous deposits.

The first of my cases was a boy, eleven years of age, whose father and mother were alive and in good health; one sister of the mother died from tuberculosis some years previously; the child had often been to see her and was kissed by her. In August, 1894, he fell ill with pleurisy on the right side; the attack lasted fifteen days but he seemed to recover perfectly. In November he suffered from cough; in February, 1895, he lost his appetite, became very weak, suffered from abdominal pains, and went into the hospital on March 1st. On admission he was thin and feverish, his evening temperature being 38·5° C. His tongue was thickly coated and he had no appetite, but there was no vomiting. The abdomen was distended, but not very painful; there was retraction of the hypogastrium, but no indication of ascites. Some obstruction was felt on deep palpation, and there was diarrhœa. The urine was normal. The patient had a little cough, and on the left side there was weak respiration with ægophony; the breath sound was rough and the expiration prolonged at both apices. Milk diet was given, a blister was applied over the left lung, and ichthyol on the abdomen. On March 7th the signs of pleurisy were increased. An enema containing nine grains of creosote was administered. On the 14th the enema was retained for eight hours and caused no pain. On the 16th an enema containing 15 grains of creosote was given. The diarrhœa had now ceased, and the condition of the left lung was also better. On April 10th slight ascites was recognised, but the abdomen was less distended and more yielding. On the 20th the amount of creosote was raised to eighteen grains, and the patient's state, both general and local, improved. On the 27th slight diarrhœa necessitated the temporary discontinuance of the creosote, as the last dose had been too large; but after a few days the treatment was resumed, and on June 25th the patient's general state was very good, the lungs and abdomen being normal. He then went into the country. I saw him on Aug. 17th, and found that the improvement was fully maintained; on Oct. 5th he set out for Cannes in perfectly good health.

My second case was that of a girl, seven years of age, whose father and mother were in good health. In 1890 she suffered from influenza and bronchitis and from frequent cough since that date. In March, 1895, her strength and appetite failed. On March 26th fever and cough set in and on the 29th she was admitted into the hospital. She was at that time anæmic and thin and had symptoms of general bronchitis; on the right side there was a harsh breath sound, with bronchophony and signs of slight dry pleurisy. There were also diarrhœa and loss of appetite, but there was no vomiting. The abdomen was distended, with some retraction in the lower part; there was no ascites; the intestines seemed to be matted together. The treatment consisted in the application of ichthyol to the abdomen and the administering of an enema with nine grains of creosote, but after some days the dose was raised to fifteen grains. The symptoms of bronchitis gradually subsided and on May 30th the abdomen was less distended, but it was necessary to make an application of collodion to it. On July 1st the abdomen was yielding and free from pain, the diarrhœa had ceased, the appetite was good, and the general health was excellent. The child weighed 20 kilogrammes (= 44 lb.), being a gain of 3 kilogrammes (= 6½ lb.). She then went home, but returned to the hospital in the month of August, having partaken too freely of fruit, which had caused diarrhœa. After some days of ordinary treatment the diarrhœa ceased and at the end of September the patient's health was very good.

Of course it is inexpedient to generalise from two cases, especially as these children were not very ill and were treated promptly; but, keeping in mind the comparatively short duration of the treatment and the necessity for preserving the appetite and the digestive functions as unimpaired as possible, it seems to me that enemata of cod liver oil and creosote are well tolerated and give good results.

Geneva.

A NOTE ON THE GLANDULAR FEVER OF CHILDHOOD.

BY DAWSON WILLIAMS, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

UNDER the name "glandular fever (Drüsenfieber)" E. Pfeiffer,[1] in 1889, described a condition observed in childhood which he contended was an acute specific fever hitherto unrecognised. The symptoms of the disorder as noted by him and elucidated by subsequent writers are briefly as follows: The patient, a child under fourteen years of age, becomes suddenly ill, the temperature is found to be raised—101° to 103° F.—there is anorexia, nausea, sometimes vomiting, coated tongue, constipation, and, perhaps, some ill-defined abdominal pain. The most prominent and characteristic symptoms, however, are stiffness of the neck, tenderness in the anterior triangle, and some pain on movement of the head and on deglutition. There may be some undue redness of the pharyngeal mucous membrane, but throughout the whole course of the illness nothing like definite pharyngitis or tonsillitis. On the second or third day a swelling is noticed in the neck, which is found to be due to three or four enlarged lymphatic glands, which can be felt beneath the sterno-mastoid muscle and along its anterior border. The temperature becomes higher and usually touches 104° F., and the ordinary symptoms of pyrexia are present. The glands, which are tender, remain swollen for from two to five days and then begin to diminish. The glands first affected are as a rule those of the left side, and the pain on movement may lead to the head being flexed towards that side. Before the glands on the left side have begun to subside those on the right begin to enlarge and in a day or two attain a size corresponding to that reached by those on the left side when at the maximum. Tenderness of the abdomen may be a very marked symptom, and in a large proportion of cases the mesenteric glands can be felt to be enlarged. The liver is enlarged almost invariably, and the spleen in more than half the cases. The other cervical glands may also become enlarged, the axillary and inguinal glands less often. The disease is mild and is seldom or never the direct cause of death, but it leaves the child in an anæmic and depressed state, which may last long after all trace of enlargement of the lymphatic glands—which has usually ceased in ten days or a fortnight—has disappeared.

It is obvious that the specific characters of the disorder are not well marked. Enlargement of the cervical glands secondary to various local lesions is of so common occurrence in childhood that the specificity of Pfeiffer's "Drüsenfieber" has not met with general acceptance. It can hardly

[1] Jahrbuch für Kinderheilkunde, Band xxix. According to Protassow (loc. cit., Band xxxii., s. 365), the condition had been described by Filatow of Moscow at an earlier date.

Hosted by Google

be asserted that his arguments have been refuted, it would be more correct to say that they have for the most part been ignored. I have for some years strongly suspected that this attitude was mistaken. I have seen in the out-patient department of the Shadwell Children's Hospital during the last few years a considerable number of cases answering to the description of glandular fever, but it is difficult in London to trace a history of infection in connexion with any of the diseases of childhood, such as, for instance, measles and whooping cough, owing to the immense number of possible opportunities of infection. Occasionally, however, I have observed several children of the same family to be affected in succession. In March, 1896, a girl aged five years was brought to the out-patient department on account of a stiff neck and swollen glands. The child looked ill, had a temperature of 102·8° F. carried her head stiffly, and on the left side there was a swelling about the size of a hen's egg by which the sterno-mastoid was bulged forward. On palpation the swelling was found to consist of three glands lying beneath the muscle. They were tender, but the child appeared to suffer more if the head were moved than when the glands were manipulated gently. She had refused food, but had not complained of pain in swallowing. On examining the fauces no acute process could be observed, the tonsils were not enlarged, the pharynx was not injected and contained only a few chronic granules. Chronic granular pharyngitis is, however, so commonly present in children inhabiting the East-end of London that it is quite the exception to find a child over three years of age free from it. The child complained of pain in the abdomen; the liver was enlarged, the spleen could not be felt nor any enlarged glands in the abdomen. There was no enlargement of the glands in the axilla or groin. The cheeks were flushed, but there was no rash, no coryza, and no cough. I saw the patient again forty-eight hours later. The swelling on the left side had decreased, but there was now a large tumour in the corresponding situation on the right side. No other glands were enlarged. The temperature was 102·5°. She complained bitterly of pain in the abdomen, for which I could discover no cause. The bowels had acted once after a dose of castor-oil, but she was till constipated, refused food, and complained of headache. Five days later I was asked to see her brother aged three and a half years. He presented a swelling on the left side in the same situation as that from which his sister had suffered. It was felt to be due to three enlarged glands beneath and near the anterior border of the sterno-mastoid muscle. There were a few granules in the pharynx, but no active mischief and no tonsillitis. The temperature was 102° and he complained of pain in the abdomen. Two days later the glands on the right side of his neck were enlarged. The temperature was raised on this day, but I have no note of its height. His illness was altogether much milder than his sister's. She remained anæmic for five or six weeks and the cervical glands subsided slowly. Eventually she made a complete recovery. On questioning the mother I ascertained that a week or more before the girl was taken ill an elder brother had suffered from a very similar but mild attack, the glands first on one side of the neck and then on the other having become enlarged. He had not been very ill with it and had had no medical treatment.

The girl's case was fairly characteristic and of average severity. The most distinctive point is that the swelling and tenderness of the glands occur without obvious lesion of the pharynx and tonsils, and are altogether disproportionate to any slight pharyngitis which may be present. The several glands can be distinguished on palpation; the skin moves freely over them and is little, if at all, reddened. The spontaneous subsidence of the adenitis is also noteworthy. I have not met with a case in which suppuration occurred, and, according to all writers on the subject,[2] this is an accident which does not occur, or occurs very rarely. The glands affected are, no doubt, those which are liable to become enlarged in affections of the pharynx; but according to my observation tonsillitis causes at first enlargement only of the highest of the deep cervical glands—that which lies on a level with the angle of the jaw. If the lower glands become enlarged it is at a later date and to a less degree. The glands which first become enlarged in association with dental disorders are those which lie transversely along the inner aspect of the lower border of the body of the inferior maxilla. Even in acute pharyngitis it is, according to my observation, very unusual to observe an enlargement, sudden and almost or quite uniform, of all the deep cervical glands. Moussous[3] lays stress on the severity of the general symptoms, which in one of the cases he records, raised a suspicion of typhoid fever. In both the cases, which he gives at length, the child, on the third or fourth day of its illness, suffered from a paroxysmal cough ending in vomiting, but without the characteristic whoop or glairy expectoration of whooping cough. This appears to indicate that the tracheo-bronchial glands may be enlarged during the course of the illness.

Pfeiffer observed that the disease occurred in very limited epidemics generally affecting a single family, but attacking most of the members who had not passed childhood. Those writers who, after Pfeiffer, have described cases have laid stress upon the absence of any discoverable local lesion capable of accounting for the adenitis. The pain on swallowing is attributed to the enlargement of the glands, for pharyngitis, even when present, is only in very rare cases severe. Hesse,[4] one of the most recent writers on the subject, reports three cases in the same family, all of whom suffered from severe nephritis. Heubner, Starck, and others have recorded cases in which the same complication occurred. Hesse argues that the existence of this complication is strong evidence in favour of the specific theory, and argues that the lymphadenitis is either a manifestation of an acute specific disease *sui generis*, or of an abortive form of one of the exanthemata. He dismisses the second alternative rather lightly, but it may be observed that rubella is believed by some to occur occasionally without rash but with marked swelling of the glands along the sterno-mastoid muscle. Further, some evidence exists to show that mumps may occasionally affect the lymphatic glands of the neck without any discoverable inflammation of the parotid or other salivary glands. It is, however, unnecessary to labour this point, because a recent communication made by Dr. Park West to the New York Academy of Medicine[5] seems to me to refute all objections of this order. The epidemic which he describes affected a sparsely populated district of Eastern Ohio. It began in the spring of 1893, continued in the cooler months of 1894 and 1895, and ended in the spring of 1896. Altogether 96 cases were observed in the district (all in the practice of Dr. F. A. Korell); about 40 others were known to have occurred, but the attacks were so mild that medical advice was not sought, and the disease was heard of also in adjacent districts. The 96 cases occurred in forty-three families; the youngest patient was aged seven months, the oldest thirteen years. In the families infected about twenty children between these ages escaped. The characteristic feature in all the cases was enlargement of the cervical lymphatic glands. The patient was seized suddenly with fever; on the second or third day an elongated swelling, uniform to the eye but on palpation found to be due to three or four enlarged glands, was perceived beneath and towards the front of the sterno-mastoid muscle. It was first perceptible in most cases on the left side, reached its maximum in from two to four days, and then began to subside. A little before the enlargement of the glands on the left side reached its maximum the corresponding glands on the right side began to be swollen and tender. Other glands in the immediate neighbourhood were slightly swollen, and in three-fourths of the cases either the post-cervical, the axillary, or the inguinal glands became enlarged also. In thirty-seven cases, or nearly two-fifths, the mesenteric glands could be felt to be enlarged, while in three-fourths abdominal pain and tenderness were present. The spleen was enlarged in more than half the cases, the liver in nine-tenths. In the mildest and shortest cases only was there diarrhœa. In the severer there was constipation, the beginning of convalescence being marked by the passage of thin greenish fæces mixed with mucus. The more active symptoms lasted from four to seven days, but the total duration of the illness varied from nine to twenty-seven days, the average being sixteen days. The glands did not suppurate in any case, and no permanent enlargement remained. For some days

[2] Except Neumann; but it is, I think, clear that many of his cases were examples of ordinary secondary adenitis, and he himself did not consider that the disorder he described was identical with Pfeiffer's "Drüsenfieber" (quoted in Jahrbuch für Kinderheilkunde, Band xxxvii., s. 430, from the Berliner Klinische Wochenschrift, 1891, No. 53).

after defervescence the pulse remained rapid and the patients were depressed. In 4 cases only was there severe pharyngitis; in 29 others there was increased redness of the mucous membrane of the throat and mouth, but it was not attended by swelling, was not marked, and did not last long. Only 1 patient died, a delicate child convalescent from scarlet fever. The suggestion that the epidemic might have been an aberrant form of mumps was considered, but was rejected; neither the parotid nor any other salivary glands were affected in any of the cases; no case of ordinary mumps occurred in the district during the time these cases of glandular fever were occurring, and 57 of the 96 children had mumps before, or at some date after, the fever. A dull flush of the skin was noticed, but no eruption in any case, and it is difficult to believe that so many cases of rubella could have occurred without the rash being noticed in any of them.

The incubation period cannot be stated positively. Hoerschelmann[6] thought it was usually from eight to ten days in his cases, with extremes of five and fifteen days. Park West states that "many more children came down on the seventh day after exposure than upon any other day."

As to the pathology of the condition there is, in the absence of any bacteriological investigations, much room for difference of opinion. Comby[7] suggests that it is due to "an attenuated streptococcic infection, of which the point of entry is probably the surface of the tonsils." He would therefore appear to be opposed to the view that the condition should be considered an acute specific infection, and this seems to be the view also of Ashby and Wright.[8] Comby, however, relies, I gather, largely upon the observations of Neumann, who found staphylococci in certain glands which suppurated, and Comby also speaks of cases in which suppuration occurred. All other writers, however, comment on the absence of suppuration as a characteristic of the disease. The constant presence of obstinate constipation led v. Starck[9] to advance the theory that the general symptoms and the adenitis might be due to infection derived from the intestines or to the absorption of a toxin from the retained fæces. Dr. Henry Koplik, in the discussion at the New York Academy of Medicine, suggested that the earlier affection of the glands of the left side of the neck, which has struck most of those who have published notes on the disease, might be due to passage of the infective agent from the thoracic duct to the glands on the same side. On the whole, however, it seems probable that the infective agent, whatever it may be, obtains entrance by the pharynx or tonsils without producing a local lesion there, as is sometimes the case with the bacillus tuberculosis.

The condition presents certain analogies to the "non-venereal bubo," which has recently attracted a good deal of attention in the Far East, and has been the source of not a little perplexity to the medical officers of the army and navy.[10] In connexion with the theory that the glandular fever of childhood is due to intestinal infection and toxæmia it is interesting to note that Surgeon-Major Skinner[11] has suggested that as the "non-venereal buboes" in the cases he observed invariably occurred in the inguinal glands, and as the patients always had irregular action of the bowels and sometimes dysentery, and in others apparently constipation, the enlargement of the inguinal glands may be due to secondary infection from the mesenteric lymph glands.

Since the body of this paper was written I have read with much interest Dr. Cantlie's statement, in his address published in THE LANCET[12] that in Hong-Kong he had become familiar with an idiopathic glandular enlargement occurring in children in an epidemic form. The enlargement, he states, involved usually only one gland in the neck over the sterno-mastoid, but at its anterior border. Apparently, therefore, the adenitis affected the superficial and not, as in Pfeiffer's "Drüsenfieber," the deep cervical lymphatics. Whether this difference is important, and whether the Hong-Kong cases are more nearly allied to the form with which I have been dealing, or to "pestis minor" it would be useless to speculate, but the observation is interesting and may turn out to be of much epidemiological importance.

Though the pathology of glandular fever is unknown, it is of practical consequence to recognise that children are liable to an affection such as I have endeavoured to describe; that it is communicable; and that, though acute and accompanied often if not usually by high temperature, it is almost invariably benign, and does not lead to suppuration of the affected glands; but that it leaves behind it marked anæmia and general deterioration of health from which the child does not completely recover for a month or two.

There is one other point in which the affection resembles a specific fever. Treatment does not, so far as I have observed, or so far as can be gathered from the literature, exercise any influence over the course or duration of the malady. A cold compress to the neck or, in the more severe cases, belladonna fomentations relieve the local symptoms but do not prevent the onset of adenitis on the opposite side. The bowels respond readily to laxatives, but the constipation soon returns. Purgatives, such as calomel, do not produce any more permanent effect, and Dr. Park West states that in some of the cases in which resort was had to this practice it seemed to be responsible for greater depression and a more prolonged convalescence.

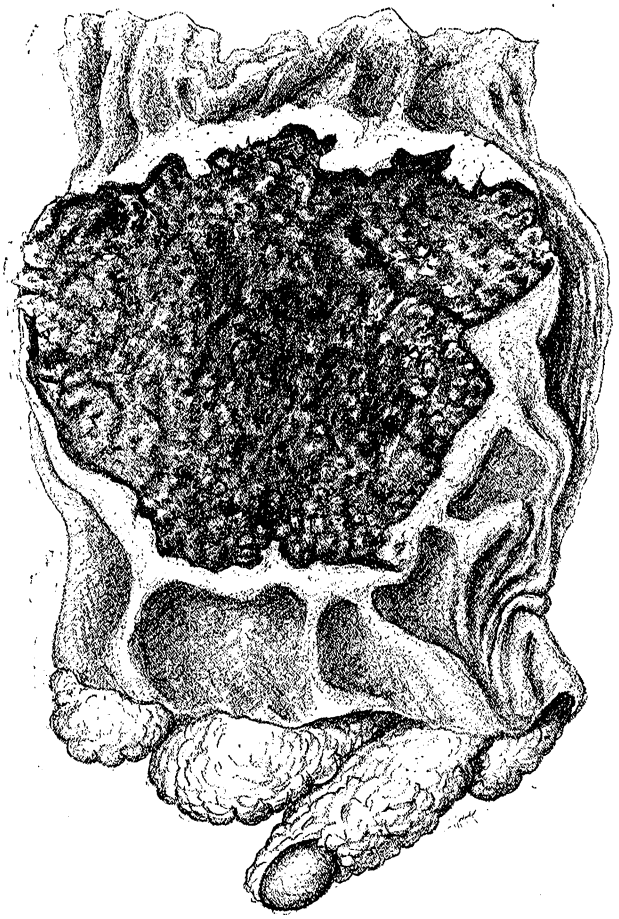
A CASE OF EXCISION OF THE UPPER HALF OF THE RECTUM FOR CANCER.

BY J. JACKSON CLARKE, M.B. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE NORTH-WEST LONDON HOSPITAL; PATHOLOGIST AND CURATOR OF THE MUSEUM AT ST. MARY'S HOSPITAL.

SINCE 1885, when Kraske described a procedure by which the upper part of the rectum and as much of the sigmoid flexure as might be wished could be removed, this operation has been frequently performed. In this country Swinford Edwards,[1] Paul,[2] and Littlewood[3] have published cases. The present position of the treatment of rectal cancer has been recently dealt with by Heidenhain,[4] who says: "The rule that rectal cancer can only be dealt with successfully when the upper limit of the growth can be reached by the finger introduced at the anus no longer holds good. The only local contra-indication to the operation is the extension of the growth to the prostate, bladder, or ureter." As a contribution to the literature of the subject the following case may be of interest.



The patient, a man aged fifty-one years, was sent to me at the North-West London Hospital on Dec. 5th, 1895. He had had no important illness until he began to suffer with intestinal symptoms five months before he came to me. First he noticed streaks of blood in the stools; then followed attacks of troublesome constipation which alternated with diarrhœa. On digital examination from the anus the lower margin of a typical cancerous ulcer could be felt. It appeared to be about an inch above the base of the prostate. Although pale and thin the patient appeared to be sound save for the local disease. In order to make sure that the growth had not extended to the bladder or ureters a median abdominal incision was made on Dec. 19th, and it was found that though the growth was of considerable size it had not extended through the peritoneal aspect of the bowel and was moveable. The median opening was then closed and a left inguinal colotomy done; the sigmoid was drawn well down and its uppermost portion was fixed in the wound. The bowel was opened on the fifth day. Both the median incision and the colotomy wound were firmly united on the tenth day. It was found that though most of the fæces escaped by the colotomy opening still some went down by the rectum, and no means we could devise were found to obviate this. I had performed the operation by Harrison Cripps's rather than by Maydl's method, because the latter might take up too much of the sigmoid and so render it difficult to draw down the rectum later. An attack of influenza, which weakened the patient, delayed the next step. On Jan. 18th, when the patient was well again, he was anæsthetised and placed on the left side. An incision was made from the tip of the coccyx. The lower part of the incision lay in the middle line, and the upper inclined to the left edge of the sacrum below the

posterior inferior spine. The coccyx and the tip and the left edge of the sacrum as far as the level of the third sacral foramina were removed. In doing this the sacro-sciatic ligaments, some fibres of the gluteus maximus, the left lateral, and the median sacral arteries were divided. There was smart hæmorrhage, which yielded to pressure of cloths, wet with hot carbolic lotion. The posterior surface of the rectum was now exposed, and it was found that the lower end of the growth was opposite the fourth sacral vertebra. The peritoneum was opened on each side of the bowel below the growth and the affected part of the bowel was drawn down into the wound; the fat and glands in the hollow of the sacrum having been removed indiarubber tubes were passed round the bowel above and below the growth and the section of the bowel including the growth and three-quarters of an inch of sound gut above and below it were removed. The divided ends of the rectum

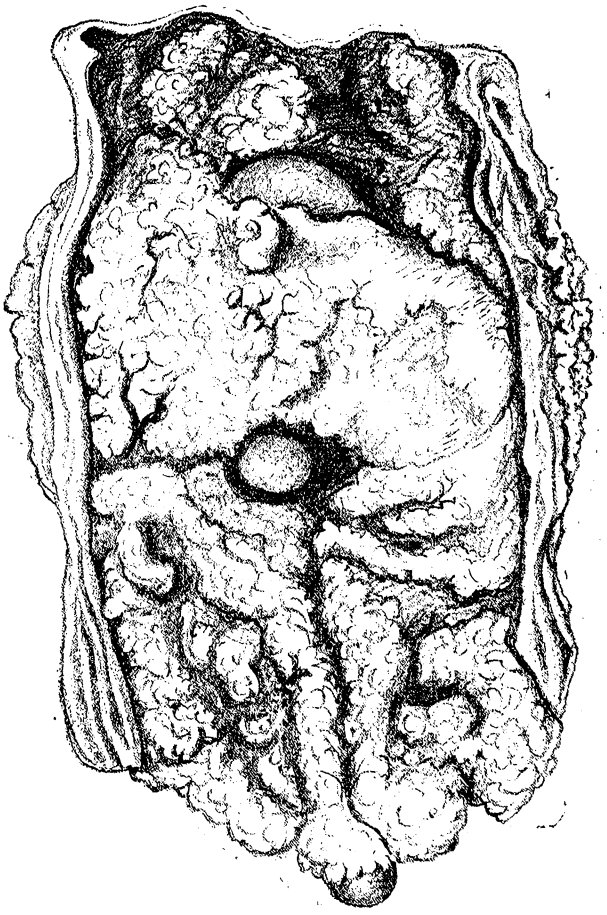

FIG. 1.

in the anterior three-fourths of the circumference were carefully united by silk stitches, which passed through the whole thickness of the gut, the posterior fourth being closed by Lembert's sutures. The peritoneum was then stitched in front of the rectum, and the skin-wound was stitched in its upper three-fourths, the lower fourth being packed with sal-alembroth gauze. There was nothing noteworthy in the progress of the case until the fourth day, when a distinct rise of temperature (103° F.) was observed, and it was found that some of the Lembert's sutures had given way, allowing the escape of fæcal matter. The wound was cleansed and glycerine and iodoform syringed into it. After this the wound healed rapidly by granulation, but left a large fistula. Two attempts to close the latter by a plastic operation having failed a linear proctotomy was done under cocaine infiltration in order to join the fistula and anus together. There remained only to close the artificial anus in the groin. After freshening the edge of the mucous membrane at the opening the latter was closed by a continuous silk suture passing through mucous membrane alone. The peritoneum was next opened all round the orifice and a row of Lembert's sutures placed outside the continuous suture. After this had been done a high-pitched, whistling note was heard, due to wind escaping from the bowel, so a second row of Lembert's sutures was placed outside the first. The bowel was then dropped back into the peritoneal cavity and the parietes were closed over all. The patient only complained of not being allowed enough to eat after this operation. I showed the patient at the North-West London Clinical Society on Oct. 21st, 1896, nine months after the operation. The patient was then in perfect health and for the last three months had been working full time as a carpenter, his employment being in making the roof of a house eighty feet high. He has one

FIG. 2.

Shows the posterior view. There is an enlarged gland embedded in fat opposite the middle, and a second at the lower end, of the preparation. (Natural size.)

good motion daily and by means of a hollow rubber colotomy plug suspended by rubber bands the opening below the sacrum is comfortably closed. He can relieve himself of flatus without removing the plug. I have to thank my senior colleague for much valuable counsel in the conduct of the case and Mr. Stroud Horsford, house surgeon, for great care and diligence in watching the case.

I am informed by Dr. W. M. Whittaker, who put the case in my hands, that he saw the patient a month ago, eleven months after the removal of the growth, in apparently perfect health.

Remarks.—1. The preliminary exploratory operation. In most cases this would be advisable, as in my opinion it is, with few exceptions, in all cases of cancer of the colon. The information thus gained may decide as to whether a palliative or a radical operation is to be done. In many cases the growth is adherent to neighbouring parts, and any traction

Hosted by Google

results only in rupturing the bowel and allowing fæcal matter to escape into the peritoneal cavity. Such a condition can only be ascertained by an exploratory operation, the only contra-indications to which are (1) when the growth can be fully explored from the anus and (2) when acute obstruction is present and the position of the block is localisable. 2. The preliminary colotomy. In the case under consideration this proved to be almost useless, and the experience suggests that unless necessary to relieve distension of the bowel it would be better omitted. 3. The operation. The great drawback is the tendency to the formation of a fistula. This is not due to any want of vitality in the rectal tissues, but to the fact that the state of the patient towards the end of the operation does not usually allow time for doing a linear proctotomy and then carefully stitching the ends of the bowel by Maunsell's method. If some method safer than that by Murphy's button and equally rapid could be applied there need be no hesitation in closing up the whole wound, and then in conditions such as that described above I should be inclined to preserve the coccyx by turning it down in a skin flap and to apply one of the methods of osteoplastic section of the sacrum, so that no important muscular or ligamentous attachments need be interfered with.

Old Cavendish-street, W.

THREE CASES OF LEAD POISONING,

WITH A NOTE ON A SIMPLE METHOD FOR THE DETECTION OF LEAD IN ORGANIC FLUIDS.

BY JOHN HILL ABRAM, M.D. LOND., M.R.C.P.,

ASSISTANT PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY; ASSISTANT TO THE PROFESSOR OF PATHOLOGY, UNIVERSITY COLLEGE, LIVERPOOL.

(FROM THE CHEMICAL PATHOLOGY DEPARTMENT, UNIVERSITY COLLEGE, LIVERPOOL.)

I HAVE had the opportunity during the past year of observing three cases of lead poisoning which are of some interest. The following is a condensed report of the cases, two of which were of the cerebral type and were under my care in the Liverpool Royal Infirmary.

CASE 1.—A man, aged twenty-six years, was admitted on July 2nd, 1896, suffering from "choky" pain in the abdomen, cramps in the legs, and fits. He had been a house painter for eleven years. He stated that he was temperate. In August, 1895, when working on the interior of a church, he had an attack of colic and eight fits. In December, 1895, while painting on board ship, he again had colic and four fits. The present illness began while he was working on the outside of a church. He was seized with pain in the abdomen, walked home with difficulty, and at once went to bed. He had several fits before his admission into the Infirmary. The patient was a well-nourished man, slightly anæmic. He was in a very collapsed condition, the pupils were small, and did not react to light. He complained of temporal headache and of sleeping badly. The legs and feet were painful and there was some tenderness on pressure. No distinct wrist-drop was present, though there seemed to be some extensor weakness. The plantar reflexes were active; the knee-jerks were absent. There was no optic neuritis. The teeth were poor and ill-kept. A well-marked lead line was present. The breath was very foul, the tongue was coated, and there was marked thirst. The bowels had not acted for forty-eight hours. There was general pain in the abdomen, which was relieved by steady pressure. The radial artery was not thickened and the pulse showed rather poor tension. There was no hypertrophy of the heart. The specific gravity of the urine, which was loaded with albumin, was 1025. It contained no sugar or casts. On the night of admission the patient was delirious, and on July 3rd he had a typical epileptiform convulsion, in which the tongue was bitten, and urine passed. He had two similar fits in the course of the day. On the 4th the bowels were cleared out by an enema and kept acting by saline purgatives. From this time he had no further return of the pains or fits and he left the hospital on July 13th practically well. The urine, I may add, was free from albumin. At no time was there any œdema.

CASE 2.—A man, aged thirty-three years, was admitted on Sept. 8th, 1896, for colic. He had been a plumber all his working life. For the last four years he had had repeated attacks of colic, usually accompanied by vomiting. For the last year he had had headache with the attacks. On admission he was found to be emaciated and anæmic. There was no œdema; the muscles were flabby; there was no paralysis; the knee-jerk was present; and there was no headache or optic neuritis. The patient slept badly. His teeth were poor and there was a well-marked blue line. He had pain in the abdomen, which was relieved by pressure and not aggravated by taking food. The bowels had been costive for three days. Vomiting was a troublesome feature of the case; the vomited matter was frothy, green, sour-smelling, and contained lead. The urine was of specific gravity 1011, neutral, and contained a trace of albumin and lead. The urea amounted to 400 grains per diem. He remained in this condition in spite of treatment (no iodide of potassium was given) until the 24th, when he was found to have become semi-comatose. On the 25th he had slight hiccough. The coma gradually deepened and he died on Oct. 1st.

Necropsy.—Slight thickening of the dura mater along the superior longitudinal fissure was found. The sub-arachnoid fluid was excessive. The brain appeared to be healthy. The lungs were congested and œdematous. The heart was normal. The mucous membrane of the stomach was dark in colour and deeply congested. The liver was rather firm and the kidneys were slightly fibroid. Microscopic examination of the liver revealed a slight amount of degeneration in the cells. In the kidney there was a slight interstitial and chronic inflammation. A chemical examination of some of the organs was made by Mr. Marsden and myself in the usual manner, and Dr. Kohn kindly determined the exact amount of lead present by the electrolytic method. The results of our examination may be contrasted with those obtained in Dr. Davidson's case[1] and the first reported in Thorpe's "Dictionary of Applied Chemistry" as follows:—

	Thorpe.	Davidson.	Abram.
Brain	29·9	29·9	20 parts per million.
Grey matter	40·9	—	22 ,, ,,
White matter... ...	18·9	.....	18 ,, ,,
Liver...	47·7	—	8 ,, ,,
Kidney	15·5	—	2 ,, ,,
Stomach	—	—	13 ,, ,,

The similarity of the amount of lead found in the three cases is striking as regards the brain, but the disagreement in the case of the liver and kidney is very marked and I can offer no explanation for it.

CASE 3.—One of my colleagues at University College, who had been working with red lead, suffered from griping pain in the abdomen and slight diarrhœa. The urine was found to contain lead. I report this trivial case for reasons I shall give in the last paragraph of my paper.

Cases 1 and 2 are examples of the cerebral forms of lead poisoning, the first the epileptiform and the second the comatose variety. As is not unfrequent in these cases colic was present. A feature of Case 1—viz., the contracted insensitive pupils—has been noted in encephalopathia saturnina by Tanquerel des Planches.[2] The general prognosis, as given by Tanquerel, that the epileptiform variety is more dangerous than the comatose is just reversed in my two cases. The treatment adopted in both cases was expectant—that is to say, the further ingestion of lead was checked for the time at any rate, milk diet was given, and the bowels kept open by saline purges. In Case 2 various remedies were tried to relieve the vomiting. In neither case was iodide of potassium given, so that "unlocking" of fixed lead cannot be given as the cause of the fatal coma of Case 2. I lay stress upon this, as iodide of potassium is alleged to give rise to cerebral symptoms in this way in rare cases. The expectant treatment was adopted in consequence of Tanquerel's statement that, in cerebral lead poisoning at any rate, it gives far better results than a vigorous line of treatment, blistering, venesection, and so forth. Careful questioning of the patients and relatives brought to light no trace of any neurotic inheritance, so that I can offer no suggestion as to the reason why these two patients should have suffered from cerebral symptoms. The considerable quantity of albumin present in the urine in Case 1, must, I think, be attributed to the convulsions, as it speedily disappeared when they

[1] The Liverpool Medico-Chirurgical Journal, July, 1896.
[2] Lead Disease, Dana's transl., 1848.

Hosted by Google

ceased, and there was no evidence of any organic affection of the kidneys.

It will have been noticed that in Case 1 there is no mention made as to the presence or absence of lead in the urine. This is due to the fact that at the time I did not know of any accurate and rapid method for the detection of lead in urine, and I had not time to carry out the ordinary procedure—viz., the destruction of the organic matter by boiling with hydrochloric acid and chlorate of potash, the resulting solutions being subjected to the ordinary tests or preferably, as Dr. Kohn[3] has shown, to electrolysis. Dr. Kohn has informed me that in urine the preliminary destruction of the organic matter may be omitted. This is a great advantage; nevertheless, it requires a certain amount of apparatus, platinum dishes, and so forth, and I have come across in Von Jaksch's "Klinische Diagnostik" a method both simple and accurate. The method seemed so simple and so little known that I confess I mistrusted it. I therefore proposed to Mr. Prosper Marsden that we should test the method thoroughly; this we have done, and can vouch for the accuracy and delicacy of the modified method[4] we now adopt. "A strip of pure magnesium is placed in the fluid to be examined. Ammonium oxalate in the proportion of about 1 gramme to 150 c.c. is added. If lead is present it is deposited on the magnesium. A deposit is seen within half an hour, but we have usually left it twenty-four hours. The slip is then washed with distilled water and dried. Confirmatory tests: (1) warm the slip with a crystal of iodine—yellow iodide proves lead, cadmium may be ignored; (2) dissolve deposit in HNO_3 and apply usual tests." The magnesium can be used again after careful washing with acid and distilled water. The surface of the magnesium must be bright—free from oxide—when used. The delicacy of the method has been tested with aqueous solutions containing known quantities of lead, also with normal urine to which known quantities of lead have been added. In all cases a control experiment was performed to ensure the freedom of the materials from lead. Without going into details I may say that we have been able to detect lead when present in the proportion of 1 part to 50,000, whether in simple aqueous solution or in urine.

It is hardly necessary to add that this simple and accurate test may be of the greatest value in certain obscure cases when, as Dr. Oliver[5] says in his Goulstonian Lectures, "So insidiously are the symptoms [of chronic lead poisoning] developed, and so variable, that not only do we, as physicians, occasionally fail to refer the illness to its proper category, but medical men, the authors of pamphlets on lead poisoning, and who, therefore, have had practical experience of the poison in others, have themselves suffered from the malady without being aware of the nature of their illness." Again, when there is no tartar on the teeth, the blue line on which such stress is laid as a diagnostic feature may be absent, and this, too, in cases which are usually obscure. This affords a further, and, in my opinion, a stronger reason for bringing forward such a simple method as the one described above.

Liverpool.

NOTES ON STONE IN THE BLADDER.

By D. F. KEEGAN, F.R.C.S. Eng.,
BRIGADE-SURGEON-LIEUTENANT-COLONEL, INDIAN MEDICAL SERVICE (RETIRED).

II.[6]—Comparative Safety of Litholapaxy and Lateral Lithotomy in Boys.

Mr. H. Gilbert Barling of Birmingham has published some valuable statistics[7] on the comparative safety of suprapubic lithotomy, lateral lithotomy, and litholapaxy in young males in England. The figures he deals with are not very large; nevertheless, his statistics go to prove that lateral lithotomy and litholapaxy are safer operations in boys than suprapubic lithotomy is at present, and Mr. Barling is of opinion that if suprapubic lithotomy is to be adopted as a routine practice in the future in boys, it must be shown that it gives better results than it does now. Mr. Barling's opinion will, I think, be shared by all those who have had a large experience in the treatment of stone in the bladder, and, as a matter of fact, surgeons in India had long ago arrived at the same conclusions as Mr. Barling, for the operation of suprapubic lithotomy in boys has made no way whatever in India, and I may add that it is never likely to do so. At the beginning of last year my friend, Surgeon-Colonel O'Connell Raye, Inspector-General of Civil Hospitals in the Punjab, issued a circular to all civil medical officers serving in the circle of his administration calling for the submission of returns showing the number of operations performed for stone in the bladder on boys up to the age of fifteen years during the year 1895. Knowing the interest I have taken for many years in the question of the relative mortality of litholapaxy and lateral lithotomy in boys, he has very kindly placed at my disposal all the returns forwarded to his office in response to his circular, and the information contained therein is embodied in the table appended:—

TABLE II.—*Showing Number and Nature of Operations for Stone in the Bladder performed on Boys up to Fifteen Years of Age, in the Punjab, during the Year 1895.*

Nature of operation.	Number of operations.	Average age of patients (in years).	Average weight of stone removed (in grains).	Average stay in hospital after operation (in days).	Percentage of mortality.
Litholapaxy	509	6·35	151·54	6·53	2·35
Lateral lithotomy	267	6·90	201·07	24·01	5·24
Suprapubic lithotomy ...	2	10·0	996·5	38·0	*Nil.*
Median lithotomy	2	6·0	155·0	18·0	*Nil.*

Seven hundred and eighty operations were performed on boys for stone in the bladder during the year under review, and the returns submitted were received from forty-eight civil hospitals and branch dispensaries scattered throughout the Punjab. The first thing which strikes one on glancing at the table is that there were but two suprapubic lithotomies and two median lithotomies performed in the year. It will be as well to dispose of these four cases at once before proceeding to an analysis of the litholapaxies and lateral lithotomies. A boy aged thirteen years with a stone weighing 3 oz. and 108 grains, and which was adherent to the wall of the bladder, was submitted to operation of suprapubic lithotomy in the Mayo Hospital, Lahore, on June 5th, 1895. He remained in hospital fifty days and was discharged cured. I think there can be little doubt that the operation selected was the correct one. A boy aged seven years was submitted to suprapubic lithotomy in the branch dispensary of Jellalabad in the Ferozepore District on Sept. 11th, 1895. There were no small lithotrites in this Branch Dispensary, and the choice of operation lay between a suprapubic and a lateral lithotomy. The stone, uric acid, weighed 445 grains, and the boy remained under treatment twenty-six days and left the hospital cured. In this case I should say that a lateral lithotomy would have answered equally well. The two median lithotomies may be dismissed in a few words. Both operations were performed at the Civil Hospital, Amritsur, and in both cases litholapaxy was contra-indicated for the following reasons. In one case a lateral lithotomy had been performed elsewhere eighteen months previously; there were a number of stones in the prostatic urethra and one large one in the bladder. The calculi removed weighed 290 grains, and the boy aged five years left the hospital cured nineteen days after operation. In the second case lateral lithotomy had been performed twice elsewhere; there were a fistula and an urethral stricture present. The stone, 20 grains in weight, was half in the bladder and half in the prostatic urethra; the boy's age was seven years; he was discharged cured seventeen days after operation.

And now to consider the litholapaxies and lateral lithotomies. The table speaks for itself. A glance at it shows that the litholapaxies were nearly twice as many as the lateral lithotomies. The average age of the patients was

Hosted by Google

nearly the same in both operations; but the stay in hospital after lateral lithotomy was four times as long as that which followed litholapaxy. The average weight of stone removed by lateral lithotomy and litholapaxy was in the proportion of four to three respectively, and the percentage of deaths after litholapaxy was less than half of that which followed lateral lithotomy. A percentage mortality of 2·35 in 509 litholapaxies in boys is, I consider, a most creditable result, and it must not be forgotten that not a few of the operators were native assistant surgeons and hospital assistants. I may state for the information of those who are unacquainted with the rules laid down in India regarding the submission of hospital returns, that the results of all surgical operations are arranged under four separate columns or headings—viz., "cured," "relieved," "discharged otherwise," and "died." My experience has been that when the result of any operation is tabulated in the "discharged otherwise" column it may be pretty safely concluded that the patient was *in articulo mortis* when removed from the hospital by his friends or relatives. Occasionally it happens that a patient discharged "otherwise" will recover, but the exception only proves the rule. And, therefore, in estimating the rate of mortality expressed in the table appended, to be on the safe side, I have counted all cases "discharged otherwise" as deaths. The table appended shows that year by year litholapaxy is ousting from its pride of place the time-honoured lateral lithotomy in boys, and doubtless when the branch dispensaries throughout the calculous districts of India are fully equipped with lithotrites, evacuating cannulæ, and efficient aspirators, lateral lithotomy, even in boys, will seldom be performed. To fully equip numerous branch dispensaries throughout India with these necessary instruments costs a large sum of money; but no doubt in time they will be supplied. Had all the branch dispensaries in the Punjab been amply supplied with small lithotrites the number of litholapaxies in boys would have been considerably greater in 1895 than it was. The superiority of litholapaxy in boys over its two rivals, lateral and suprapubic lithotomy, is now fully established throughout the length and breadth of India, and to show how it has risen in the estimation of those best qualified to appraise its value I shall quote the deliberate opinions of some of the most experienced surgeons in the Punjab when submitting the returns of stone operations for the year 1895. One surgeon who has treated a very large number—several hundreds—of stone patients during his career writes: "I consider this [litholapaxy] the only legitimate operation for removal of stone from the bladder when the conditions are suitable." This surgeon was obliged to perform a lateral lithothomy on a boy aged four and a half years, and he writes: "In this case the urethra was so narrow that the smallest lithotrite, No. 6 (Weiss), could not be passed and lithotomy became a necessity. *I consider lateral lithotomy infinitely superior to suprapubic lithotomy when the stone is of small or moderate size.*" Another very experienced surgeon writes: "If I may give an opinion I should say that an operator of experience, with good instruments, would remove stone by litholapaxy in 19 children out of 20." In this surgeon's district 34 boys were treated for stone in the bladder during the year 1895, and one and all were cured. Again, a third surgeon writes: "Out of 33 cases, litholapaxy was performed in 29, lateral lithotomy in 3, and lateral lithotomy with lithotrity in one case, with very successful results—i.e., 1 death in 33 cases. The operation of litholapaxy in children is generally resorted to in cases where there is a likelihood of an easy removal of débris within a reasonable time, and the stone can be caught by the lithotrite that could be passed through the urethra into the bladder. The advantages in experienced hands are little danger and speedy recovery. Moreover, the patients and their friends do not like the cutting operation and often go away without relief if they come to know that lithotomy will be necessary." Were it necessary to do so I might quote similar opinions held by several other experienced surgeons in the Punjab. The Indian peasantry are now fully alive to the advantages which litholapaxy possesses over lateral lithotomy, and they have begun to manifest a very decided aversion to any cutting operation for the relief of stone in the bladder. And hence it is that patients living in out-of-the-way villages undertake long journeys to the well-equipped hospitals in the large towns and cities of the Punjab when they learn that branch dispensaries are not supplied with the instruments necessary for the crushing operation. The hospitals at Rawal Pindi, Multan, Amritsur, Jullundur, and Lahore have acquired a great reputation for the successful treatment of stone, and patients flock to them in great numbers from distant places. And the same holds true of other provinces of India.

Mr. Jonathan Hutchinson, in his address in Surgery at the annual meeting of the British Medical Association held in London in 1895, did me the honour of citing me as an example of personal specialism in crushing stones in children. Some eight or ten years ago, before the operation of litholapaxy in boys had been placed on a firm and lasting basis in India, and when I was combating theoretical objections to its extension to children, and before others had followed my example as they have done of late years, it is possible that I may have been more expert at crushing stones in children than some of my fellow workers in India. But I am happy to think that I cannot now lay claim to any such distinction, for there are scores of surgeons in India at the present day who can crush a stone in a child's bladder as well, if not better, than I can. To give the reader some idea of the popularity of litholapaxy in boys I may mention that in the year 1895, in the Multan district alone, 69 boys were treated for stone in the bladder. In 64 of these cases litholapaxy was successfully performed and the 5 remaining were treated by lateral lithotomy. Surgeons in India are not, and never have been, enamoured of suprapubic lithotomy in its application to small uncomplicated stones in young males, and they have steadily refused to follow in the footsteps of their brethren in this country and in Europe generally.

The history of the revival of suprapubic lithotomy in England is in some of its aspects a curious one. Submitted to the favourable consideration of British surgeons by its distinguished advocate, Sir Henry Thompson, as the best method of dealing with very large stones in adult males and youths, it was suddenly seized upon by a number of inexperienced lithotomists, as the safest method in their hands, of dealing with small stones occurring in male children, and the good old lateral lithotomy which had stood the test of time and had proved so successful in boys, had to give way to its fashionable rival. But the pendulum has swung back, and Cheselden's operation will regain the position it should never have lost in the treatment of stone in young males. But brilliant and successful as lateral lithotomy has proved itself in dealing with the great majority of calculi which the surgeon meets with in young males, it must not be forgotten that in three very important respects it is an inferior operation to a well-performed litholapaxy. The cure is more rapid and the percentage of success is greater in litholapaxy than in lateral lithotomy, and litholapaxy can claim the additional advantage that it is an operation in which the knife is not used. Any surgeon who in the present day is compelled to cut a young boy for a small, uncomplicated stone is, in my opinion, not to be envied; for with the good example set him by surgeons in India he cannot but feel that either through the lack of suitable instruments or by his own inability to use them with precision and safety, his young patient is being deprived of the benefits of a very distinct advance in surgery. He cannot but be aware that such a stone would be best extracted by a successful litholapaxy, and still from want of practical familiarity with the use of the lithotrite he hesitates to crush the stone and consigns his little patient to the dangerous ordeal of the knife. Mr. Reginald Harrison, in the "Twentieth Century Practice of Medicine," vol. i., in discussing the relative advantages of lateral lithotomy and litholapaxy in male children, comes to the rescue of such surgeons and gives them some crumbs of comfort in the following remarks: "Many practitioners who are expert lithotomists would fail to find the same success in their application of the crushing operation to male children. Some instances have been recorded where the bladder was ruptured in performing lithotrity, and it is probable that we should have further examples of this if the practice were much extended." True, deplorable accidents have occurred in the course of a litholapaxy in boys, but the number of such has not been very great. As well might one discountenance the operation of lateral lithotomy by enumerating the occasions on which some very distinguished surgeons have missed the route to the bladder in its performance. The fact of the matter is that hitherto, in discussing the relative advantages of lateral lithotomy and litholapaxy in male children, the subject has been viewed too often from the surgeon's standpoint when by rights, it should be considered from the standpoint of the little patient and his friends and relatives.

The best operation for a boy, say, of seven or eight years with an urethra of normal calibre suffering from the presence of a small uncomplicated stone is unquestionably litholapaxy. Such being the case, the question arises, Is a surgeon justified in cutting such a boy because he happens either not to have the necessary instruments for performing litholapaxy or, having them, does not know how to use them? I unhesitatingly answer, No, if by any possibility such a patient can be transferred to the care of one skilled in performing litholapaxy. The crushing of a stone in a boy's bladder is not an operation which every general surgeon in this country is expected to be able to perform. It is an operation for those who have enjoyed unusual opportunities of perfecting themselves in the use of the lithotrite, and it is not on all fours with operations of emergency, such as tracheotomy, the arrest of hæmorrhage, an amputation, or an operation for strangulated hernia. No surgeon who has been deprived of opportunities of learning the practical use of the lithotrite need be ashamed to confess that he feels himself unequal to peforming litholapaxy on a young boy. The extension of litholapaxy to cases of stone in boys has reduced the mortality following stone operations among this class of patients in India by more than 50 per cent. to what it was ten or twelve years ago. This is a fact, and a very important one, and one, moreover, which cannot be any longer ignored. It would, therefore, be well if surgeons in all civilised countries were to carefully note the very important work which is being done at the present day in India in the surgery of stone in the bladder, and it would also be well if they would shape their practice in accordance with the methods which obtain in this unrivalled field for experience in this special branch of surgery.

THE PATHOLOGY OF ALBUMOSURIA AND PEPTONURIA.

BY JAMES KENNETH WATSON, M.D., C.M. EDIN.,
LATE HOUSE SURGEON, ESSEX AND COLCHESTER HOSPITAL.

VERY little information has been forthcoming of a definite nature to explain the occurrence of these morbid phenomena, and in discussing their pathology we must rely on conjecture to a considerable extent. There are three possible sources of albumosuria and peptonuria. In the first place they may be derived from the gastro-intestinal tract; in the second place it is possible that the albumoses and peptone may be formed in the blood itself; and thirdly, morbid conditions in the tissues may result in their formation and excretion in the urine.

In considering their derivation from the intestinal tract we are at the outset beset with a difficulty, for we do not really know the precise change by which the albumoses and peptone are regenerated into the proteids of the blood; in other words, the exact physiology of the process has not yet been revealed. We have to be content to say that the change takes place during the actual process of absorption, that the gastric and intestinal mucous membranes effect the change, and that the change is a vital one. If, then, we do not know precisely how the change is brought about, it is not easy to formulate deviations from what normally takes place.

Faults may arise in connexion with the absorption process and these may come about in many different ways. By an excess of peptone being formed we can understand that the "equilibrium" of metamorphosis, so to speak, might be put out of gear, resulting in either the excess of peptone or possibly even all the peptone being absorbed, more or less, unchanged. Again, by faulty chemical processes the albumoses might fail to be completely hydrated and be absorbed either in the primary or the secondary stage as such. It is quite reasonable to suppose that diseases of the stomach or intestine, such as inflammation, degenerations of various kinds, or malignant disease, might so interfere with the vital action of the cells concerned in the metamorphosis as to render them more or less functionally inactive; as a result of such a condition absorption, ceasing to become a vital act, might become merely a mechanical or passive process. Even where there is no organic lesion in the gastric or intestinal mucous membrane it is possible that functional neuroses may modify the process of the metamorphosis of peptones materially, for there can be little doubt that the vital action of the absorbing cells is completely regulated by the nervous system. Reflex inhibition of the action of these cells, therefore, such as might arise from mental emotions of various kinds, or even from unsuitability in the quantity or the quality of the food ingested, in fact, from all causes of functional dyspepsia, might, we may argue, allow of peptone, or even of the albumoses, being absorbed more or less unchanged. That such has not yet been proved to be the case speaks very highly for the wonderful way in which the stomach and intestines do their work. The passage of the albumoses and peptone unchanged through the gastro-intestinal mucosa constitutes, then, one of the possible sources of albumosuria and peptonuria.

The theory already brought forward might serve to explain some cases of chronic dyspepsia with dilated stomach where peptonuria has been found, and also some cases of malignant disease in which it has been found to occur. Can this theory of the absorption of the albumoses and peptone, more or less unchanged, serve to explain some cases where chronic dyspepsia is associated with anæmia, toxic headache, and constipation, these bodies acting as poisons in the blood? The chief argument against such an hypothesis would lie in the fact that albumosuria and peptonuria have not been described, so far as we know, in this class of cases; but the detection of these bodies in the urine has only lately been perfected. Although so far this conjecture has nothing to support it from the clinical point of view, yet it is permissible. We shall consider later the question as to the possibility of these bodies which have been absorbed into the blood being destroyed there, and on this account not being able to be detected in the urine.

Let us next turn to the tissues as a source of albumosuria and peptonuria. We shall find that most of the cases which have been described have been referred to morbid conditions in the tissues. In this connexion we must remember that Hofmeister[1] and others believe that during digestion some of the peptone is absorbed unchanged. Probably extremely little peptone passes into the blood as such, and therefore this may for all practical purposes be eliminated under normal conditions. If we grant, however, that some peptone does become absorbed unchanged, we may ask, Does the amount absorbed vary under normal conditions, and if it does vary, what are the limits and how is the quantity kept within these limits? In considering the tissues as a source of albumosuria and peptonuria we are supposing that the gastro-intestinal tract is doing its work and that these bodies are undergoing their normal metamorphosis. Under what circumstances, then, may the albumoses and peptone be formed in the tissues? Hofmeister[2] points out the affinity shown by peptone towards the white blood corpuscles, for he considers that the peptone absorbed from the alimentary canal is contained in this element of the blood and not in the serum. When, as a result of inflammation, or more especially of suppuration, disintegration and death of the leucocytes takes place with formation of pus, then it is probable that the cell proteids, which are identical with, or closely allied to, the blood proteids, are converted into albumoses and peptone. Just as this action takes place in the stomach and intestines in the presence of a ferment, so it is reasonable to suppose that the same process may occur in the tissues. What is the exciting cause here? We may suppose that the change may be set up by bacteria contained in the pus or else by ferments, possibly allied to the digestive ferments, set free by the disintegrating and dying leucocytes.[3] Albumoses and peptone have been described in pus by Eichwald[4] and Hofmeister[5] among others; but Sidney Martin[6] has, however, shown that the methods adopted by these workers were not entirely trustworthy; he recommends that the pus be kept under excess of alcohol for several weeks, when after drying and extracting the albumoses and peptone remain in solution, the other proteids becoming coagulated. If, then, pus contains, or may contain, albumoses and peptone we have a clue to their presence in many

of the diseases where albumosuria and peptonuria have been described as occurring.

We may probably go further than this and say that in cases where there is not actual pus formation, but where a great cell-disintegration takes place, there we may have the formation of these bodies. Hence we may include not only such cases as abscesses, empyemata, and purulent inflammations of such serous membranes as the peritoneum, but also diseases where we know a great cell-disintegration takes place, such as phthisis, malignant growths, pneumonia, the specific fevers and phosphorus poisoning (where peptonuria has been described as occurring[7]), and, indeed, all, or nearly all, those diseases where albumoses and peptone have been found in the urine. On the same grounds we can explain the presence of hetero-albumose or Bence Jones's albumin in the disease known as osteomalacia or mollities ossium, where it has been described as occurring both by him,[8] Kuhne,[9] and others; in this disease a prominent feature is the osseous disintegration whereby the bones become gradually decalcified.

In such cases as the ones we have been considering why should we have both albumoses and peptone formed? We must probably look on the formation of the albumoses as a stage towards the final formation of peptone, as we do in digestion, the complete change depending on the activity of the bacteria concerned in the process. It would be interesting to bear out Oertel's[10] observations by examining the urine of men engaged in severe manual labour, such as blacksmiths, navvies, &c., with a view to ascertaining if the cell disintegration dependent on their work resulted in the formation and excretion in the urine of albumoses and peptone. We can hardly believe that these bodies are formed in every case where great cell disintegration occurs, or else albumosuria and peptonuria could not fail to be far more common than they are. We can only say, therefore, that when excreted in the urine there is either a probability of pus formation or great cell disintegration in the body—that is to say, when we have reason to believe, as we usually have, that their derivation is from the tissues. The relation of the albumoses and peptone to the fever process is one full of interest. There is no doubt that the immediate cause of the heat generated in fever lies in the increased blood and tissue oxidation, which signifies a rapid metabolism. It is an enticing theory to assume that the micro-organisms associated with the majority of the different fevers with which we are acquainted act on the tissues, setting free or giving rise to the formation of the albumoses and peptone, and that the rise of temperature is proportional to the dose of albumose and peptone absorbed into the blood, the temperature thus forming an index to the amount of cell disintegration taking place. The artificial introduction into the circulation of albumoses and peptone produces a rise of temperature which gives support to this view. Probably poisonous constituents derived from these bodies play an important part in causing this rise of temperature.

Lastly, the blood itself must be considered as a possible source of the albumoses and peptone. There is, however, little or no evidence to show that albumosuria or peptonuria may arise from the formation of these bodies in the blood or to prove the dependence of these symptoms on their derivation from the tissues. Yet we may argue that bacteria act upon the blood proteids, transforming them, as in the case of the cell proteids in the tissues, into albumoses and peptone. If this does occur we must believe that it takes place under much the same conditions as govern the formation of these bodies in the tissues. It is more probable, however, that the action of the blood towards the albumoses and peptone is a hæmolytic rather than a hæmogenic one; and this conclusion is based upon the comparative infrequency of albumosuria and peptonuria when contrasted with the frequency and variety of those diseases in which these phenomena have been described as occurring. This can largely be accounted for by insufficient and inaccurate analysis of the urine in those diseases where we might expect to find albumosuria and peptonuria were a systematic and accurate examination carried out. Yet it is hard to believe that the occurrence of albumoses and peptone in the urine is proportional to their absorption into the blood from the alimentary canal or from the tissues in disease. We know that a portion of the peptone produced in the alimentary canal is further acted upon by the pancreatic juice and is split up into leucin and tyrosin, &c., and that this is designated "hemi-peptone" to distinguish it from the remainder of the peptone, "anti-peptone," which resists this action. Why, we may ask, should not this change occur in the tissues or even in the blood? If the agent is present which can transform the cell proteids and even the blood proteids into albumoses and peptone, why should not the process go a stage further? We know that putrefaction is not necessary for the formation of leucin and tyrosin, although their formation is favoured by it. Is it not possible that the hemi-peptone formed in the tissues is in whole or in part further acted upon by the agent which produced it, while the anti-peptone resists this change and is excreted in the urine? Or, to go a step further, it may be suggested that where peptonuria occurs, there the peptone is present as anti-peptone; whereas in many cases where we should expect to find peptonuria we fail to do so, for only hemi-peptone has been produced and has been broken up into simpler bodies which we cannot detect in the urine. An objection to such a suggestion is the absence, in most cases at any rate, of leucin and tyrosin and those bodies into which hemi-peptone is split up from the urine in those cases where, expecting to find peptone in the urine, we fail to do so.

It is highly probable, however, that leucin and tyrosin have some relation to the excretion of peptone in the urine, for tyrosin and peptone have both been found in the urine in at any rate one morbid state—namely, in acute phosphorus poisoning,[11] where we know a great cell disintegration takes place. It is probable that the morbid anatomy of the liver in cases of acute phosphorus poisoning closely corresponds with that of the liver in acute yellow atrophy or malignant jaundice, where we know a prominent feature in the disease is the occurrence of leucin and tyrosin in the urine. One might argue, therefore, that in certain diseases of the liver, characterised by great parenchymatous degeneration with disappearance of the liver cells, peptone may be found in the urine, but where it is absent then the bodies formed from its disruption would replace it. So far as we know, however, leucin and tyrosin have not been found, at any rate at all frequently, in poisoning by other agents, such as arsenic, antimony, or alcohol, or even in malignant disease of the liver, where the morbid anatomy of the organ corresponds to a greater or less extent in its broader features—namely, the degeneration and sometimes the ultimate destruction of the liver cells—with that of acute phosphorus poisoning, although peptonuria has been described in at least one morbid condition of the liver.

The clinical side of this question requires further investigation. We shall then be in a better position to understand the pathology of the excretion of the albumoses and peptone in the urine and their relation to disease.

TRAUMATIC TETANUS TREATED BY HYPODERMIC INJECTION OF CARBOLIC ACID; RECOVERY.

BY ARTHUR EDDOWES, M.R.C.S. ENG., L.S.A.

A MARRIED man, aged forty-one years, received a punctured wound on the inner side of the ball of the left great toe from a boot nail on or about May 19th. Little notice was taken of the wound at the time and he continued his work. On the 26th he got very wet and thought he had contracted a chill. About June 2nd the wound was observed to suppurate slightly, but he still did his work. On the 9th he felt slight stiffness of the lower jaw and of the nape of the neck; the latter sensation was described "as if something was constantly pulling his head backwards." On the 10th the symptoms being slightly worse, he consulted his medical man, who prescribed for him. He visited the practitioner again on the 11th and 12th, but he still continued his work.

[11] Quain's Dictionary of Medicine, vol. ii., p. 1144, and reference No. 7.

Hosted by Google

On the morning of the 13th he was advised by the medical man to go home and go to bed, but he did not do so till 6 P.M. During these days the symptoms had been steadily increasing in severity and by the 13th his condition was as follows. The patient's jaws were quite closed, so that slops only could be taken. The muscles of the back were slightly rigid, sufficiently so to make movement difficult. By the next morning (June 14th) there was fully-developed trismus with severe aching pains in the muscles around the lower jaw, rigidity and arching of the neck, rigidity and slight arching of the back, and some contraction of the abdominal walls; the lower extremities were not much complained of except for shooting pains round the knees; the upper extremities were free. The urine passed normally; the bowels were acted upon by two grains of calomel given the previous evening; the surface of the body was somewhat clammy. The pulse was 66 and of good volume and the temperature was 98° F. His intellect was clear; the power of swallowing was not perceptibly affected, the patient being easily fed with slops owing to the absence of several teeth. Treatment consisted in the administration of chloral hydrate and bromide of potassium every four hours and liquid food. On the 15th the arching of the neck and trunk was somewhat more extreme; the trismus was still marked, and there was some degree of risus sardonicus observable. Also there was considerable pain complained of, beginning in the spine and shooting forwards. The power of the extremities, however, remained good; the urine passed normally, but the bowels were not open. The pulse and temperature were the same as on the 14th. On the 16th his condition remained unchanged. On the 17th occasional momentary convulsive movements of the trunk, simulating hiccough, were observed, the arching of the neck and trunk was increased, and the power of the lower extremities was slightly lessened. There were considerable pain and some tenderness of the spinal column. The pulse was 72 and the temperature was normal; the urine passed normally, but it was highly concentrated and loaded with urates; the bowels were opened by an aperient and enema. On the 18th the rigidity of the neck was less extreme, the convulsive twitchings were more frequent, and intense fœtor of the breath was noticed; otherwise the condition remained the same as on the 17th. A consultation was held and the following treatment was adopted. Highly nourishing diet was ordered, consisting of eggs with milk and brandy, milk with soda water, jellies, and cocoa, frequently administered in small quantities. Ten grains each of chloral hydrate and bromide of potassium were administered every two hours. Five minims of carbolic acid (2 per cent. solution) were injected hypodermically morning and evening. The chloral and bromide of potassium were given at 8 P.M. and were followed by intense excitement with numbness in the extremities half an hour later, which continued during the greater part of the night. The carbolic acid was injected at 10 P.M. and no after-effects were noticeable, the pulse being 102 and the temperature 100·8°. On the 19th, at 10.45 A.M. the pulse was 96 and the temperature 100·8°. The patient had become quieter, the convulsive movements were less frequent and less severe; he took his food well; his intellect was somewhat clouded, but he was conscious of his surroundings. There was less rigidity of the back, chest, and abdomen, and more power in the legs; there was no change in the degree of the trismus. The bowels were inactive, and an aperient and enema had to be resorted to. On the 20th the pulse was 90 and the temperature was 99·8°. The convulsive movements were very slight during the night, but the patient was very restless. The rigidity of the back, chest, and abdomen was much lessened, the back completely resting on the bed; there was greater power in the lower extremities, but little change in the rigidity of the neck. The mouth could be slightly opened, but not sufficiently to allow of protrusion of the tongue. The bowels were still inactive, and an enema was given. The patient's condition considerably improved by the afternoon and the treatment was slightly changed, the hypodermic injection of carbolic acid being reduced to once daily and the chloral and bromide being given every three hours instead of every two hours as before. On the 21st the pulse was 72 and the temperature normal. The patient had had a restless night, but less so than the preceding one. The rigidity of the muscles was lessening, with the exception of those of the neck, which remained firm. The movement of the jaw was more complete and there was less risus sardonicus. The bowels, however, had not been opened, in spite of a dose of castor oil. The hypodermic injections were discontinued and fifteen grains of chloral hydrate were given three times a day. On the 22nd the pulse was 78 and the temperature 98·2°. The rigidity had almost disappeared except in the neck and jaw. The patient was still restless, evidently from being confined to bed, and the bowels were still inactive, but the patient's condition was improving. On the 23rd the pulse was 73 and the temperature normal. He had had a good night, but felt depressed. There were no paroxysms, but there was some pain in the back. The rigidity had considerably diminished and the lower jaw was slightly more moveable. As the bowels remained inactive, an aperient was given. Food was well taken. A tonic was prescribed. From this time the patient made a steady and uninterrupted recovery, and after a month at Scarborough returned in perfect health.

NOTES ON THE PHOTOGRAPHY OF RENAL AND VESICAL CALCULI BY THE X RAYS.

BY A. P. LAURIE, M.A., D.SC.,
AND
JOHN T. LEON, M.B., B.SC. LOND.

OUR first experiments were made on museum specimens with a view to determining how far different calculi were opaque to the x rays and comparing their opacity with flesh and bone. The resulting plate[1] showed conclusively that calculi composed of oxalate or phosphate of lime were more opaque than bone, uric acid calculi of almost the same opacity, and gall-stones very slightly more opaque than flesh. We note that Mr. Henry Morris in THE LANCET of Nov. 14th, 1896, has substantially confirmed our results. These results seemed to show that there should be no serious difficulty in photographing stone in the kidney or bladder.

After some inconclusive experiments on living subjects we next inserted a uric acid calculus of about ⅝ in. in diameter into the kidney of the cadaver of a man about fifty years of age. This was done with as little disturbance of surrounding parts as possible. We used to photograph the stone, a "focus" tube and an induction coil giving a 6 in. spark with four storage cells connected to the primary circuit, and took the photograph on a "Lightning Cadett" plate. After an exposure of thirteen minutes with the body lying on its back the plate was removed and developed and showed a faint but distinct image of the stone, though the spine itself was very faintly indicated.

The next experiment on a living subject gave a negative result which was subsequently confirmed by operation. The next case was that of a boy aged eight years who came to the out-patient department of St. Mary's Hospital in November, 1896, with the symptoms of vesical calculus. On this occasion we used the same induction coil and the same number of cells and an xxxxx Paget plate, the exposure to the rays being seven minutes. The accompanying collotype A (taken from the untouched negative) shows the result, the calculus being apparently a little over an inch in diameter. Within the next few days lithotrity was performed by Mr. Silcock, a No. 9 lithotrite being used and the detritus weighing ninety-eight grains. It was composed principally of uric acid and was oval in shape. Within a few days of the above case we had another, that of a boy aged about fifteen years, in whom a skiagraph showed the presence of a calculus in the bladder quite distinctly.

"A NOTE ON THE OCCURRENCE OF METRORRHAGIA AFTER THE MENOPAUSE IN CASES OF OVARIAN TUMOUR."

BY J. B. HENDERSON, M.D. BRUX., L.R.C.P., L.R.C.S. EDIN.

IN the interesting paper by Dr. Lewers in THE LANCET of Jan. 2nd under the above heading I notice the following sentence: "It may fairly be concluded that the occurrence of bleeding from the uterus after the menopause in cases of ovarian tumour is a somewhat rare event"; and I therefore feel justified in sending you the following note of a case at present under my observation. A woman aged sixty-one years, in whom the menopause occurred about fourteen years ago, has noticed a swelling in the abdomen for two or three years, and although she thought that it might be something serious for the last two years, she only complained of it about a month ago. I then examined her and found signs of a large cystic tumour probably connected with the right ovary and about the size of a seven months' pregnancy. She says that the tumour has been growing more quickly during the last few months, and that within the last eight months she has had on three or four occasions a hæmorrhagic discharge, which lasted for about two days and made her think that her monthly periods were returning.

A CASE OF LAND SCURVY.

BY S. HAMILTON, B.A., M.B.R.U.I.

THE following case is interesting from the rarity of such a condition at the present day and also from the fact that the usual causes of scurvy did not exist. The patient was a man aged forty-one years, tall and thin, who had worked underground in the Ferndale Collieries for years. His previous health was not robust; he was a sufferer from chronic dyspepsia, but was able to work till April, 1896. His habits were fairly regular, except a partiality for whisky and snuff. The first symptoms of scurvy appeared about the end of last April. The gums were swollen, soft and spongy, and bled on the slightest friction. His face had a peculiar sallow yellowish hue and was anæmic, with puffiness under the eyelids. He complained of lassitude and pains in his limbs, stiffness of his joints, and dyspnœa on fatigue. At this stage a satisfactory diagnosis could not be arrived at. Shortly afterwards he took to his bed and fresh symptoms appeared. Large irregular, ecchymotic patches were seen on his legs from the knees downwards; there was œdema of the legs, feet, and ankles; the pains in the legs and thighs were more severe; the gums became more turgid, spongy, and tender, and bled more easily; the teeth became loose; his breath had a remarkably offensive odour, which could be perceived outside his bedroom; hard swellings, very painful on palpation, were to be felt in the calves of the legs. At this stage there could be no doubt as to the nature of the case. All the most approved remedies for scurvy, both dietetic and therapeutic, were administered one after another without any improvement in the symptoms. The patient became gradually more emaciated and exhausted; the pulse was slow, weak, and thready; the first sound of the heart and the impulse were weak; the urine was scanty and dark red in colour and had an ammoniacal odour; the alvine evacuations were generally free and offensive; and towards the end melæna was present. During the last month of his life the only food tolerated by the patient was fresh eggs beaten up in a little brandy. At this period the œdema of the legs and ankles disappeared—this being the only symptom that showed any improvement. Towards the end of July the patient died from exhaustion, about three months after the first symptoms appeared.

Sporadic cases of land scurvy of this nature and of such severity are rare. In this patient none of the usual causes of scurvy could be traced. He had never been to sea and had always used fresh vegetables as part of his food. The circumstances that he was a sufferer from chronic dyspepsia and that he was thus reduced to a state bordering on starvation may have been factors in the causation of his malady.

EDINBURGH ROYAL INFIRMARY.

A CASE OF ENORMOUS PRIMARY SARCOMA OF THE LIVER IN WHICH A LARGE BLOOD CYST SIMULATING A HEPATIC ABSCESS WAS DEVELOPED; ASPIRATION, ETC.; NECROPSY.

(Under the care of Dr. BYROM BRAMWELL.)

THE carefully observed record of the case which we give this week will be much appreciated by our readers, for it is of much value from many standpoints. The occurrence of sarcoma as a primary growth of the liver is very rarely observed, and a complete account of such a case, with the addition of the bibliography on the subject is a gain to medical and pathological literature. The majority of cases which have been observed of primary sarcoma of the liver are mentioned in this paper; there are two others which are referred to by Sajous.[1] 1. That of a girl, aged twenty-two years, under the care of Dr. G. Wach,[2] in whom the growth was mistaken for hydatid cyst. 2. A primary sarcoma in a child, aged four months, reported by Dr. Lendruf.[3] The abdomen was enormously distended; there was no jaundice. The liver contained numerous disseminated tumours of a light red-brown colour.

A married woman aged twenty-five years was admitted to Ward 5A, Edinburgh Royal Infirmary, on June 23rd, 1894, complaining of debility, emaciation, shortness of breath, and pain in the lower part of the right chest at a point two and a half inches below, and slightly external to, the right nipple. The patient stated that she was quite well until her marriage, three months before. Since then she had suffered from pain in the right side in the position described above. She thought it was worse in wet weather. At first it was intermittent and of a dull, aching character, but lately it had been more constant, sharp, and boring. The patient attributed her illness to catching cold. At the commencement of the attack she was troubled with a dry cough, but there was no expectoration; the cough continued for two or three weeks and then disappeared; the pain, however, remained. In other respects she had been fairly well, though getting weaker. Her appetite and her digestion had been good, though she had been somewhat troubled with flatulence. She had noticed that the right side of the chest had recently become more prominent than the left. The patient stated that until the present illness commenced she had always enjoyed good health. She had never lived abroad and had never suffered from dysentery, diarrhœa, or any affection of the bowels. She last menstruated some six weeks previously. The patient was one of a family of five; four were living, being strong and healthy, and one died at the age of six years from tuberculous meningitis. Her father and mother were both alive and well. So far as she knew none of her relatives had suffered from any liver affection. On admission the patient was pale and thin; she looked extremely ill. She lay on her right side; she said that the pain was worse when she attempted to move or when she lay in any other position. There was no jaundice. The evening temperature was about 100° F. and the morning temperature

98°; the pulse varied from 110 to 120. The right side of the thorax over the region of the liver (infra-mammary and hypochondriac regions) looked fuller than the left. The bulging was most marked in the position of the fifth, sixth, and seventh interspaces in the anterior axillary line. The sternum appeared to be pushed forward and there was some fulness in the epigastrium. A localised tender spot was present in the sixth right interspace in the anterior axillary line. The apex of the heart was displaced upwards and to the left; it corresponded to a point slightly outside, and on a level with, the left nipple. The liver dulness was greatly increased. In the mammary line it extended from the third rib above to a point an inch above the umbilicus. Posteriorly there was marked dulness over the lower part of the right chest; the dulness extended as high as the spine of the scapula; its upper border was curved and corresponded in shape to Garland's S-shaped curved line representing the upper limit of the dulness in a moderately large pleuritic effusion. The breath sounds, vocal fremitus, and resonance were absent over the dull area. On the left side of the chest the breath sounds were harsh and bronchial in character and the vocal fremitus was well marked. The heart appeared to be normal. The splenic dulness also seemed to be normal. The tongue was red, congested, and dark-looking, not furred or tremulous. The appetite was good. The patient was troubled occasionally with flatulence. The bowels were costive. The urine was of a dark reddish-brown colour, clear, acid in reaction, and its specific gravity was 1014. The deposit, which was considerable, consisted of amorphous urates and uric acid. The urea equalled 1·3 per cent. The urine contained no bile, blood, albumin, or sugar. On the evening of the patient's admission to hospital a diagnostic puncture was made by the house physician into the right pleural sac, but no fluid was withdrawn. On June 25th a hypodermic needle was passed into the right chest at the tender spot between the fifth and sixth ribs and some dark anchovy-paste-like fluid, highly suggestive of an abscess of the liver, was removed. On microscopical examination it was found to consist of red blood corpuscles, leucocytes, and broken-down cellular elements, apparently liver cells. On the 26th fifty-three ounces of dark anchovy-paste-coloured fluid were withdrawn with the aspirator; the needle was passed into the liver at the position of the tender spot between the fifth and sixth ribs. The fluid which was withdrawn consisted of white blood corpuscles, red blood globules, broken-down cells, granular débris, and a few large cells, apparently liver cells in process of necrosis and fatty change. The amount of blood which the fluid contained was much larger than one expects to find in an abscess of the liver. The removal of the fluid was followed by marked relief both to the breathing and the pain. On the 27th the patient felt better; she was quite free from pain; her expression was less anxious-looking, but she was very pale, and the pulse was quick (120), the respiration was 32, and the temperature 98·8°; there had been little or no rise of temperature during the night. The tongue was moist, red, and speckled with a white fur. On the 28th it was noted that during the night she suffered a good deal from pain in the right shoulder. She still complained of pain and the cavity in the liver appeared to be filling up. There was some œdema of the skin in the right hypochondriac region. On July 1st the distension of the right side of the thorax was quite as marked as it was before the aspiration; the cavity in the liver had evidently filled up. The pain and difficulty in breathing were very troublesome. The patient was very pale and weak; the pulse ranged from 114 to 120 and the respirations from 38 to 40. The feet were slightly swollen. Mr. Cotterill saw the patient with Dr. Bramwell and it was agreed to incise the cavity and to insert a drainage-tube. The operation was performed on the 2nd. Fifty ounces of anchovy-paste-coloured grumous fluid, which was more bloody than that removed by aspiration, were evacuated. On the 3rd the patient had passed a very good night. She was quite free from pain and said that she felt better. The tongue was clean and moist. The temperature was 97°, the pulse 108, and the respiration 106. On the 7th the wound had been dressed several times; there was a considerable quantity of bloody discharge. The patient was very pale, but in other respects looked better. She said that she had been much relieved since the operation. The tongue was clean. The appetite was so good that the nurse said the only difficulty was to satisfy her, for she was ravenously hungry. She was sleeping well. On the 9th the bloody discharge still continued in considerable quantity and the patient was more anæmic. In other respects she was well. She was ordered to have one of Robertson's (No. 3) Blaud's pill capsules three times daily. On the 10th the bleeding still continued; ice-bags were ordered to be kept continuously applied to the region of the liver. On the 17th the bleeding still continued, notwithstanding the local application of ice and the subcutaneous injection of ergotine. The patient was so profoundly anæmic that it was decided, after consultation, to close the wound. Mr. Cotterill accordingly sewed the edges of the wound closely together with horsehair and painted collodion over the surface of the wound. On the 18th the patient had suffered a good deal of pain in the region of the liver during the night. There was now some oozing through the dressing. Five minims of turpentine were ordered to be given every eight hours. On the 20th not a drop of fresh blood had escaped through the dressing since the previous morning. She had only had two doses of turpentine, one in the evening of the 18th and a second on the morning of the 19th. She felt sick; the turpentine had therefore been stopped. She complained of pain in the tip of the right shoulder. The cyst had again filled up; the right side was again much more prominent than the left; the breathing was very rapid, and the patient was profoundly anæmic and prostrate. With the object of relieving the pain and distress of breathing the cyst was again aspirated and twenty ounces of dark bloody fluid containing some pale coagula were withdrawn. On microscopical examination the fluid consisted of leucocytes, red blood corpuscles, granular débris, and a few large cells, apparently liver cells. On the 24th the patient felt very weak and prostrate, but was free from pain. There was a little leakage from the puncture. On the 26th the breathing had been so distressed during the night that the house surgeon again aspirated the cyst in two places. On percussion an area of tympanitic resonance was now present on the right side between the fourth rib and the seventh space anteriorly. On the 30th the patient died.

Pathological Report by Dr. LEITH.—The necropsy was made on July 31st, 1894, some twenty hours after death. The body was somewhat emaciated; post mortem rigidity and lividity were slight. There was a recent linear cicatrix in the sixth right interspace. It ran parallel with the ribs for about one inch from the nipple line outwards. Its outer extremity showed a small aperture about the size of a crow-quill. This led by a short sinus downwards, backwards, and inwards into a large cavity. A probe could be passed into this cavity for fully six inches and could be moved freely about in it. On opening the abdomen the peritoneum was seen to be normal, but the membrane was drawn upwards and over to the left side. The liver was more prominent than usual and projected for fully two inches below the costal margin in the line of the gall-bladder. The left lobe extended further into the left hypochondrium than usual and also projected further downwards. The right lobe just below the costal margin showed a deep groove formed by the uprising margin of a prominent, smooth, tumour-like swelling of a whitish, glistening, and fibrous appearance. This was seen over the whole lower margin of the right lobe and passed upwards beneath the ribs as a large dome-like swelling. On opening the thorax and removing the sternum with the rib cartilages, the upper surface of the liver was found to be extensively adherent by recent easily separable adhesions to the anterior part of the diaphragm. These were strongest and oldest opposite the level of the fifth rib. The large dome-like tumour already referred to was now seen to occupy the whole of the upper surface of the right lobe of the liver and to project considerably into the left lobe, displacing the suspensory ligament fully three-quarters of an inch to the left. It was uniformly round and had a glistening fibrous appearance. It rose gradually upwards, reaching a considerable height above the ordinary level of the liver in the middle of the right lobe. The appearance of the groove at its lower margin was partly due to the colon, &c., pressing the thin, inferior, lower liver border forwards. Two small apertures were seen in the anterior surface of the tumour a little above and to the right of its centre. These led into cavities in the tumour, apparently separate from one another, and a probe could be passed from the upper of the two through a small aperture in the middle of the diaphragm into the right pleural cavity. This perforation in the diaphragm was due to the puncture of an aspirator

Hosted by Google

needle shortly before death. The right pleural cavity contained a small quantity of recent lymph. On palpation of its upper surface the whole tumour gave a sense of semi-fluctuation more marked towards the right side than inferiorly and to the left. On removing the liver the inferior vena cava at its place of exit from the organ was free from clot, but at its entrance into it and for fully two inches downwards in the abdomen it contained a pale-greenish lateral thrombus adherent to its right side. It was comparatively recent, not very firm or adherent, and below passed gradually into an ordinary black clot. The vein in its course through the liver was free from clot. The structures of the anterior layer of the gastro-hepatic omentum, the hepatic artery, bile ducts and portal vein were normal and in no way obstructed. The portal vein contained no clot even in its main lateral branches. The liver weighed 9 lb. 6 oz. and measured 11½ in. transversely, 10 in. antero-posteriorly, and fully 4½ in. in thickness. The tumour was now seen more fully, and occupied, as already mentioned, nearly the whole of the right lobe and a part of the left. It projected above the upper surface of the organ though it hardly reached its under surface, which presented practically a normal appearance. It measured 7 in. in transverse diameter, 7½ in. in antero-posterior diameter, and about 4 in. in thickness. The gall-bladder was small and contracted and did not show below the lower liver border. It contained a small quantity of olive-green viscid bile. An antero-posterior section was made through the middle of the right lobe (see Figure) It showed the tumour mass occupying the whole of the right lobe, replacing the proper liver tissue everywhere except for 1 to 1½ in. towards the inferior border and a mere shell on part of the under surface. It was everywhere encapsuled by a firm, fibrous-looking capsule of varying thickness. The main mass of the tumour was composed of a structureless, red, granular, and friable material, obviously crumbling blood-clot. The rest showed lobed and irregularly rounded masses of a soft whitish-yellow, gelatinous-looking substance, reminding one somewhat of a gelatinous blood-clot. These were situated towards the inferior and posterior part of the liver. They were seen on the one hand to be clearly defined and bounded by the limiting external capsule, and on the other hand to irregularly mingle with the hæmorrhagic mass. The largest area was about the size of an ordinary orange, oval in shape, with a clearly defined fibrous-looking wall around it separating it from the hæmorrhagic mass. The same capsular appearance was seen elsewhere, but not so distinctly; and in all cases the contained gelatinous material could be easily detached and suggested the idea of a multilocular cyst into which the jelly-like substance had grown as solid ingrowths from part of the wall. Other antero-posterior sections were made both to right and left of this section and showed irregular and rounded areas of the gelatinous substance mixed up with red areas, evidently consisting of pure blood-clot or of the gelatinous material infiltrated more or less intimately with blood. What appeared to be white fibrous septa penetrated the whole tumour in several directions. Everywhere towards the left the encapsulation seemed to be perfect, but near the right border there were a few places in which it was scarcely detectable. In fact, this part showed an appearance as if separate roundish centres had become confluent. A comparison of the appearances presented by all these sections led to the opinion that the more actively growing part of the tumour lay towards the right and the oldest part to the left. The liver substance where it was still visible outside the tumour showed a distinct fatty change. It was paler than normal and presented irregular areas of congestion, but nothing else abnormal. The branches of the portal vein throughout were free from clot and the other structures of the portal spaces presented normal appearances.

Antero-posterior section through the middle of the tumour, showing a large mass of blood clot, the soft yellowish-white-looking gelatinous areas, and the well-defined capsule. The letter A points to the anterior surface of the liver. The letter U points to the upper surface of the liver. At the posterior surface the capsule is well seen. Almost the whole of the liver substance has disappeared.

None of the bile ducts were dilated. Some of the sublobular veins showed small recent thrombi in the neighbourhood of the clot evidently secondary in their nature. No growth of any kind was found anywhere else, either in any of the thoracic or abdominal viscera. The spleen weighed 5 oz. It was firm and pale, but healthy. The left kidney weighed 4 oz. and the right 4½ oz. They were both small and paler than usual, but beyond a slight waxy degeneration affecting some of the Malpighian bodies they appeared to be healthy. The stomach and intestines were quite healthy, as were also the mesenteric and retro-peritoneal glands. The bladder, vagina, uterus, ovaries, &c., were all carefully examined and found to be normal. The heart weighed 7 oz. Its valves were competent and healthy. The myocardium was somewhat atrophied and pale. The left lung weighed 14 oz. and the right only 10 oz. The upper lobe in both was anæmic and the lower œdematous. There was some collapse on both sides, but especially on the right towards the base and root. There was also some recent lymph on the base of the right lung and on the corresponding surface of the diaphragm around the puncture. The brain weighed 48 oz. It was healthy and no other lesion of any kind was found in any other structure in the body.

Hosted by Google

Microscopic examination.—Sections of the margin of the tumour showed a well-defined fibrous capsule separating it from the condensed and somewhat cirrhosed liver tissue. The structure of this marginal part of the tumour was mainly cellular, consisting of spindle and irregularly-shaped cells in a recticular-looking matrix of finely fibrillar connective tissue. The cells varied much in size and resembled sarcomatous cells of a somewhat aberrant type. Some of them were very large, with convoluted or multiple nuclei. Such giant cells, however, are not infrequently found in spindle-celled sarcomata. Many persistent bile ducts were to be seen in this part of the section. Sections of any of the gelatinous areas showed a structure characteristic of a medium-sized, spindle-celled sarcoma. The cells were long and spindle-shaped, the nuclei oval and almost rod-shaped in places. Indeed, here and there the cells closely resembled non-striped muscle cells. The intercellular substance was scanty and the bloodvessels rudimentary. Sections of the material in the large blood cyst or hæmorrhagic-looking area proved to be ordinary blood-clot. Towards its margins it became mixed with tumour cells. Many small, branched cysts lined with a single layer of endothelium were seen both in the typical sarcomatous part and at the margin of the hæmorrhagic area. They were free from contents, except here and there where the hæmorrhage around them had passed into them and partly filled them. Microscopic hæmorrhages were also plentifully seen in nearly every part of the tumour. The tumour was undoubtedly a sarcoma, tending towards the spindle-celled variety. On account of its numerous bloodvessels and the multitude and magnitude of its hæmorrhages it might be called an angeio-sarcoma. The cysts were hardly numerous or important enough to entitle it to be called a cystic sarcoma.

Origin of the tumour.—After sections of many parts of the periphery were made some were found showing an early stage of the growth. They showed columns and islands of liver tissue surrounded by the tumour cells. The latter were seen pushing themselves outwards between the columns of liver cells, and as the endothelial cells of the bloodvessels could sometimes here be made out the tumour cells apparently occupied the place of the perivascular lymphatics. This naturally suggested an origin in the connective tissue-cells lining the lymphatics. If any safe deduction can be made as to the origin of any sarcoma from the behaviour of its growing margin, then there is clear histological evidence in this case of the tumour having originated in the connective tissue cells lining the perivascular lymphatics of the intralobular capillaries of the liver. Block believes that the origin in his case was from the endothelium of these capillaries; while Hörup, in his case, traces it from the adventitia of the hepatic arteries.

Remarks by Dr. BRAMWELL.—The above case presents many points of pathological and clinical interest. The more important pathological features are: (1) The rarity of primary sarcoma of the liver; (2) the large size of the tumour; and (3) the fact that a large blood cyst was developed in the interior of the tumour. Clinically, the case is chiefly interesting from a diagnostic point of view. The physical signs exactly simulated those of an abscess of the liver. The liver was greatly enlarged; the dulness extended chiefly in the upward direction; the upper limit of the dulness was a curved line corresponding to the S-shaped curved line of a moderately large pleuritic effusion; the apex beat of the heart was displaced upwards and to the left; the right side in the infra-axillary and hypochondriac regions was enlarged and bulging. A tender spot was present in the sixth right interspace in the anterior axillary line (indicative of the "pointing" of the fluid collection). An aspirator needle introduced into this spot entered a large cavity, and from this cavity fifty-three ounces of anchovy-paste-coloured fluid (highly suggestive of an abscess of the liver) were withdrawn on aspiration. But against the diagnosis of hepatic abscess were the facts that there was no history of dysentery or other cause of hepatic abscess, and that the fluid removed from the cavity in the liver contained a much larger quantity of blood (red blood corpuscles) and a much smaller quantity of pus (leucocytes or pus cells) than a hepatic abscess usually contains, or, so far as my knowledge and experience enable me to judge, ever contains. When, after incision and drainage, the oozing of red blood continued, the original diagnosis of a hapatic abscess, which was made before and after the first aspiration, seemed negatived. I was then at a loss to account for the nature of the condition. The most likely lesion seemed to me to be a large angioma of the liver which had broken down and formed a suppurating blood cyst. And looking back at the clinical features which the case presented during life I still think that this was the most feasible diagnosis which could have been arrived at to account for all the facts of the case.

Bibliography by Dr. LEITH.—The literature of primary liver sarcoma is not very satisfactory. I have found a record of twenty-five cases, few of which, however, can be regarded as true examples. Of these, six were melanotic and three lympho-sarcomas more or less diffused. All except three of them presented the appearance of many nodules scattered more or less widely throughout the liver substance. In these three there was a large mass in the right lobe, partly gelatinous and partly mixed and infiltrated with blood. One was in a child, eight months old, recorded by West. He speaks of it as a cancer and says there were secondary nodules in the lung. From its description I think it may be justly regarded as a sarcoma. The second case is recorded by Roberts under the title of a Case of Fungus Hæmatodes of the Liver. It occurred in a girl aged twelve years, and formed a large mass weighing about 8lb. in the right lobe. The third case is recorded by Hörup of Copenhagen. It occurred in a woman aged twenty-six years and formed a mass in the right lobe measuring about five inches in all directions. It was a small, round-celled sarcoma.

BEQUESTS TO SHEFFIELD CHARITIES.—One of the executors of the late Mrs. William Overend, of West Retford House, has announced the following list of legacies left by the deceased lady to local charities:—Sheffield General Infirmary, £5000; Sheffield Royal Hospital, £5000; Sheffield Girls' Charity School, £5000; Sheffield Boys' Charity School, £2000; Sheffield Jessop Hospital for Women, £2000; Sheffield Blind Institution, £2000; Sheffield Deaf and Dumb Institution, £2000; Sheffield Children's Hospital, £1000; Sheffield Nurses' Home (corner of Hounsfield-road), £1000; Sheffield Aged Female Society, £1000; Sheffield Church of England Educational Institute, £1000; Sheffield Scripture Reader's Society, £500; Sheffield Female Protection Society, £500; Sheffield Soldiers' Home, Langsett-road, £500. The *Sheffield Daily Telegraph* reminds its readers that Mrs. Overend was not content with practising posthumous philanthropy, but that in her lifetime she gave freely to objects which commended themselves to her sympathy and judgment. For example, in 1883 she gave £10,000 to found a convalescent patients' fund to provide means for sending to suitable homes patients ready to be discharged from hospital but not sufficiently recovered to go straight to work. This fund has proved of the greatest service in supplementing the services of the General Infirmary.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Infantile Cerebral Degeneration, with Symmetrical Changes at the Macula.

A MEETING of this society was held on Jan. 12th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Dr. KINGDON (Nottingham) and Dr. RISIEN RUSSELL read a paper, illustrated by lantern slides, on Infantile Cerebral Degeneration, with Symmetrical Changes at the Macula, a rare and fatal disease of infancy, which commences in the early months of infant life by muscular enfeeblement, associated with distinctive ophthalmoscopic appearances, complete paralysis resulting later, with a fatal issue about the end of the second year. Four cases of this affection had been under the observation of Dr. Kingdon and Dr. Russell; the children were born of healthy Jewish parents, and of three other children of the family two are healthy, but one died from the disease. Of the four cases that have been under observation three are dead and one is still alive. An account was given of the clinical history of the four cases, together with a description of the morbid changes met with post mortem in the central nervous system and eyes in the three cases which died. This account was supplemented by that of another placed at their disposal by Dr. F. J. Smith. Dr. Kingdon and Dr. Russell detailed the characteristic features of the disease, their description being based on the conditions met with in the cases reported in the earlier part of their paper, in conjunction with a study of all the recorded instances of the disease. Male and female children are affected and no exciting cause can be assigned. There is no apparent relation to syphilis, consanguinity of marriage, or any of the usual hereditary diatheses; but there is a marked racial peculiarity in that all the cases recorded have occurred in Jewish children. More than one child in the same family is usually affected. The symptoms and progress of the disease occur in three stages. In the first stage a child, born at full term and healthy, begins to show signs of muscular enfeeblement and of failure of sight about the end of the third month. About the fourth or fifth month definite and characteristic changes in the region of the macula lutea can be detected on ophthalmoscopic examination. The second stage of the disease is characterised by such marked muscular enfeeblement that the child is unable to sit up, its head falls backward if unsupported, and its grasp is feeble; when in the recumbent posture there is inability to turn from side to side. It is generally apathetic and the face bears an expression of mental enfeeblement. Vision is almost abolished, but there is still perception of light, while hearing remains acute, and the sense of taste is preserved. In the third stage the enfeebled muscles become atrophied and general emaciation progresses and becomes most marked. The deep reflexes are exaggerated, and still later there is rigidity of the extremities and retraction of the head, while occasional spasmodic contractions cause the child to start and cry from pain. Convulsions are not the rule, but have been noted in two exceptional cases. The temperature remains normal throughout the course of the disease. The heart, lungs, and abdominal viscera are also normal. The characteristic ophthalmoscopic appearances consist in symmetrical changes at the macula lutea, in which situation there is a whitish-grey patch but slightly raised above the surface of the retina, with a few retinal vessels visible on it at the periphery. In the centre of the patch the fovea centralis is seen as a dark cherry-red spot. In the early months the optic papilla shows no decided changes, but later in the course of the disease there is definite optic atrophy. Subjects of this disease usually die within two years, but the duration of life varies from one and a half to two and a half years. Death is sometimes unexpectedly sudden. On macroscopic examination of the central nervous system after death little that is abnormal can be detected, but most profound changes are met with on microscopical examination. There is a widespread degeneration of the pyramidal cells of the cerebral cortex which is progressive in character, extensive degeneration of the fibres of the corona radiata and of the pyramidal tracts throughout their whole course in the pons, medulla oblongata, and spinal cord. Similar but less extensive degeneration occurs in the fillet, descending root of the fifth nerve, and superior cerebellar peduncles. As in the pyramidal system, so in these tracts, the degeneration is quite symmetrical on the two sides. With regard to the eyes, which were examined microscopically by Mr. Treacher Collins, the retina at the yellow spot is much thickened, this being due to enlargement of the outer molecular layer, the tissue of which is spaced out, the most marked changes occurring in the neighbourhood of the fovea, and becoming less evident towards the periphery of the affected area. The optic nerve is atrophied, with increase of interstitial connective tissue and a large increase of round cells in the nerve. There is cupping of the optic disc the result of atrophy of the nerve fibres. There is no inflammatory exudation between the dural and pial sheaths of the nerve. The pathology of the disease was discussed, and the possible relationship between the ocular changes and those met with in the central nervous system was considered. Dr. Kingdon and Dr. Russell had not found any treatment of value in these cases, but suggested certain lines of treatment which may possibly influence the course of the disease after it had commenced or prevent its occurrence in children liable to it. The paper was copiously illustrated by photographs representing different stages of the clinical course of the disease, and by photo-micrographs of the changes met with after death both in the central nervous system and in the eyes, and sections of the degenerated cortex were shown under the microscope.

Dr. FLETCHER BEACH had seen a similar physical and mental condition in idiots twelve years of age at Darenth Asylum. Post mortem the cases showed a degenerative condition of the cerebral cortex exactly like that described by Dr. Kingdon and Dr. Russell.

Dr. TOOTH commented on the retention of acuteness of hearing in spite of degeneration of the temporo-sphenoidal lobes.

Dr. KINGDON, in reply, considered that the retinal change which occurred in all their cases marked them off from those quoted by Dr. Fletcher Beach.

Dr. RISIEN RUSSELL said that the changes in the temporo-sphenoidal lobe were much less marked than in other regions of the brain, which probably explained the fact that hearing was unaffected.

MEDICAL SOCIETY OF LONDON.

Wandering Spleens.—Prognosis of Pneumothorax.

A MEETING of this society was held on Jan. 11th, Mr. REGINALD HARRISON, President, being in the chair.

On the motion of the PRESIDENT, which was seconded by Sir DYCE DUCKWORTH, the congratulations of the society were offered to Sir Joseph Lister on his elevation to the Peerage.

Mr. BLAND SUTTON read a paper on Wandering Spleens. He referred to their extraordinary mobility and their tendency to sink into the pelvis and simulate tumours in that position. The cause of the increased mobility was little understood, but it was noteworthy that wandering spleens usually occurred in women, and in the majority of cases the patients had had children. The effects on the spleen were:—1. Engorgement, often to an extraordinary degree, which varied from time to time. He had seen great diminution occur from contraction of the organ when exposed to the air at the time of operation. 2. Axial rotation, which again by strangling the vein led to increased engorgement. The same symptoms accompanied acute rotation as were met with in acute rotation of an ovarian cyst and in strangulated hernia. 3. Atrophy.—If the torsion was so acute as to obliterate the splenic artery atrophy of the spleen ensued, as demonstrated by Rokitansky. Effects were also produced on neighbouring viscera. The pancreas might become involved in the pedicle and forcibly elongated. He had seen a case, and Richelot had published another, in which pancreatic tissue was included in ligature of the pedicle when the organ was removed. The stomach might be drugged on, causing dilatation, along with kinking of the duodenum, and recurrent attacks of jaundice might result from tension on the common bile duct. Adhesions were apt to form with intestines. Since wandering spleens tended to gravitate into the pelvis they occasionally caused

Hosted by Google

acute retroflexion, and in one case recorded caused complete prolapse of the uterus, vagina, and bladder. This pressure also seriously disturbed menstruation. A wandering spleen might jeopardise life through causing rupture of the stomach or duodenum, intestinal obstruction, or from rupture or suppuration occurring in the spleen itself. The diagnosis was often difficult, and from their so frequently reaching the pelvis, from their shape and firmness, together with the disturbances of menstruation they caused, they were most frequently mistaken for uterine myomata. On the other hand, ovarian and uterine tumours when moveable might closely simulate wandering spleens. In one case a myoma with a long pedicle so closely resembled a spleen when the abdomen was opened that it was only by feeling the spleen in its normal position that spectators were satisfied that the tumour was not a displaced spleen. Its dark colour was due to engorgement from twisting of the pedicle. In another case he had operated on for a very moveable tumour with a notched margin the tumour was found to be an ovarian cyst, the largest loculus of which had ruptured. Smaller loculi on the surface had given the impression of splenic notches. In both cases the tumours were successfully removed. He considered that splenectomy for wandering spleen was not only justifiable, but was a highly successful operation, the rate of recovery being equal to that of ovariotomy in skilled hands. He had succeeded in collecting a score of cases performed within the last twenty years without a death. Attempts had been made by Pouwer and others to secure the spleen in the left hypochondrium by means similar to those adopted for moveable kidney, but the results showed clearly that the patients ran much greater risks and had a longer confinement to bed than if the spleens had been removed. The great difference between splenectomy and splenopexy was that in the former case the individual was deprived of an organ, and although it was not known with any degree of precision what its real use was, the surgeon was, nevertheless, bound to display caution in dealing with it. So far as his own cases went he had failed to find any evil manifestations. He regarded the spleen as a highly developed and specialised lymph gland, and at present there seemed to be no greater reason for hesitating to remove it when "wandering" and troublesome in so far as remote consequences were concerned than to excise a crowd of enlarged glandulæ concatenatæ. It was a fact that many, if not all, individuals with a wandering spleen were very thin and often gaunt, and as far as his observations went they retained this character when spleenless.—Mr. BALLANCE had seen a case two years ago with Dr. Cullingworth in which the wandering spleen was situated in the pelvis. There were great variations in bulk from time to time and acute abdominal pain and vomiting at the menstrual periods. The spleen was removed and the patient rapidly recovered from the immediate effects of the operation, but after about ten days began to suffer from a curious train of symptoms. There was some pyrexia, quick pulse, emaciation, complete anorexia, loss of strength, increased quantity of urine, and griping pains in the abdomen. There was also great increase in the leucocytes. He had seen the same train of symptoms in two adult males after excision for rupture. In a boy in whom he performed excision of the spleen the operation was not followed by any symptoms. Similar symptoms followed excision in old dogs, but young animals did not seem to be inconvenienced by the removal. In some of the cases he had fed the patients on spleens, either raw or slightly toasted. He thought the bone pains might be due to the yellow marrow becoming converted into red, the marrow taking on the function of the spleen pulp, while the lymph glands undertook the work of the Malpighian bodies. The condition of the blood became normal in about ten weeks, and all the patients completely recovered their weight and health.—Mr. BLAND SUTTON, in reply, said that none of his cases had shown the symptoms described by Mr. Ballance. He was inclined to doubt whether the administration of spleens had anything to do with the ultimate recovery. His cases were all thin before operation, but did not show any increased emaciation afterwards.

Dr. SAMUEL WEST read a paper on the Prognosis of Pneumothorax (which will appear in full in a future number), and referred to the natural course of the disease so far as it was indicated by the mortality and duration. The statements were based upon three sets of statistics: (1) 101 cases from the records of the Hospital for Diseases of the Chest, Victoria-park, published some years ago; (2) a set of 43 cases from the registers of St. Bartholomew's Hospital; and (3) 20 cases of his own (the last two series had not yet been published). The first series yielded a death-rate of 77 per cent.; the last two a rate of 60 per cent. Saussier's figures placed the mortality at about 90 per cent. In respect of duration, out of the first two series of 74 cases 45 died within the first month—i.e., 60 per cent.; and 9 more died within the second month—i.e., 71 per cent. The causes of death fell into three groups: (*a*) those in which death was the direct result of the pneumothorax itself; (*b*) those in which death was the indirect result of it and due to the complication which followed—i.e., empyema; and (*c*) those in which death was the result of the original disease to which the pneumothorax itself was due—e.g., phthisis. The three considerations usually embraced by the term prognosis required in the case of pneumothorax to be separately dealt with. They were: (1) the immediate risk to life; (2) the possible duration of life; and (3) the chances of ultimate recovery. The immediate risk to life depended upon many conditions:—(1) the urgency of the symptoms; (2) the effect produced upon the opposite lung and the amount of previous disease in it; (3) the effect upon the heart; (4) the general strength of the patient; and (5) the nature of the cause. These were briefly considered. The duration of life was next dealt with. In respect of recovery most statistics gave a percentage of not more than 10 per cent. The figures derived from St. Bartholomew's Hospital yielded over 25 per cent., and his own were more favourable still. It was of these cases of recovery that he wished to give an account. The most favourable cases were those in which no effusion took place, but the air was simply absorbed. Of this there were five instances. In another set of cases effusion formed, but it was serous, and recovery took place with or without paracentesis, just as it did after ordinary serous effusion. When the effusion was purulent the prognosis was much more grave, but even some of these cases might recover in time. The following cases illustrated recovery:—A. *Without effusion.*—Case 1. A woman, aged nineteen years, was affected with phthisis for about three months. Pneumothorax of the left side developed in the hospital, but completely disappeared without special treatment in five weeks. The phthisis made rapid progress, from which the patient died shortly afterwards. Case 2. A healthy man, aged forty-six years, was sent up by Dr. Parry-Jones of Pinxton, who discovered the pneumothorax on examination of the chest. The onset had been quite latent and there had been nothing to direct attention to the chest, the man having been at work till admission. No effusion formed and in a few weeks recovery was complete, and ten years later he was still well. Case 3. A man, aged twenty-four years, had very doubtful signs of phthisis. Right pneumothorax developed, which was tapped, but recovery took place without effusion in the course of five weeks. No physical signs developed, and the patient was known to be in his previous health for at least twelve months afterwards. Case 4. A man, aged twenty-two years, a football player, was admitted with what was apparently his third attack of right pneumothorax. This last attack resolved rapidly, and in four weeks the patient was well and remained so for months, when he passed out of observation. Case 5. An apparently healthy young woman, aged fifteen years, seen with Dr. Waldo of Clifton, developed pneumothorax without any very urgent symptoms. She recovered in the course of some weeks and remained in good health to date, seven years later. B. *After serous or sero-purulent effusion.*—Case 6. A man, aged twenty-two years, was admitted into the hospital with right hydro-pneumothorax of probably three months' duration. Three weeks later forty-three ounces of clear serous fluid were removed, and again after three weeks twenty-two ounces were taken away. From that time, nearly fourteen years ago, he had continued in perfect health. Case 7. A man, aged twenty-four years, presented well-marked signs of phthisis at the left apex. While under treatment left pneumothorax developed. Effusion formed and twenty-two ounces were removed. In a fortnight all signs of air had disappeared. A week after this there was a sudden recurrence of the pneumothorax, which also rapidly subsided, and in three weeks after the second attack the patient had lost all signs of it. Case 8. A man, aged twenty-one years, was seized with left pneumothorax without very urgent symptoms and without obvious cause. A good deal of fluid formed, but it was all spontaneously absorbed, and he made a complete recovery. Six months

Hosted by Google

later he came again under treatment with pneumothorax of the opposite side. A little fluid formed, but that was also absorbed, and again the patient recovered, and was still in good health six years after the attack. Case 9. A man, aged thirty-one years, was admitted to hospital with pneumothorax with effusion. Three weeks later eighty ounces of clear serum were removed. The fluid re-accumulated, but the patient feeling better refused any further treatment and left the hospital. C. *With purulent effusion.* Case 10. A man, aged forty-six years, was admitted with pneumothorax of fourteen days' duration. Ten days after admission he was tapped and seventy-four ounces of clear serous fluid were withdrawn. Two weeks later he was tapped again, but this time no fluid could be obtained. Shortly afterwards the puncture suppurated and a clear sero-purulent fluid was discharged. The patient improved slowly, but the sinus never closed completely, and he died from phthisis a year later. Case 11. A man, aged twenty-nine years, came under observation with left pneumothorax with some effusion. The attack had originated without definite symptoms so that its duration could not be fixed. In the course of two weeks he improved greatly and had gained three pounds. He then began to spit up pus and from this time made more rapid progress. Six weeks later he left the hospital greatly improved in general health, but expectorating some ounces of pus daily. It would have been better, Dr. West thought, to have laid the side open, but the patient refused operation. He thought that its share in the diminished mortality of other diseases of the thorax might fairly be claimed for pneumothorax, and he attributed this to the better comprehension of the true nature of the affection and its dangers and to the better treatment of the cases, especially during the early days of the attack, when the risks to life are greatest.—Sir DYCE DUCKWORTH considered the paper the most complete and important of recent years and congratulated Dr. West on his results. The most serious cases were those associated with empyema. He thought that the presence of pus in the pleural cavity was much less harmful than might be expected, and he endorsed the teaching of Sir Andrew Clark and others, that interference in such cases was usually harmful and led to rapid extension of the lung mischief.—Dr. DE HAVILLAND HALL considered the prognosis of cases occurring in the apparently healthy to be very good, the air being absorbed in about six weeks and the amount of discomfort caused surprisingly little. Many, however, developed phthisis in later life. Rest in bed, with the administration of laxatives to prevent straining at stool, was the only treatment required.—Dr. KINGSTON FOWLER believed it best to leave cases of pyo-pneumothorax alone. In one case, in which the pus contained abundant streptococci, he was obliged to draw off the fluid to relieve pressure. Death occurred not long after from rupture of one of several aneurysms of the internal mammary artery. Possibly the character of the organisms present in the pus might be of importance in deciding the course to pursue in each case. He had seen one case in which the necropsy appeared to show that the pneumothorax had been due to the bursting of an emphysematous bulla.—Dr. H. W. HUBBARD considered interference inadvisable.—Mr. G. R. TURNER mentioned a case in which pneumothorax occurred from rupture of the œsophagus during an attack of vomiting. The rarity of the condition after fracture of the ribs was curious, but he saw one case in which it occurred on the day after the accident; in this case, also, while the patient was vomiting.

Dr. WEST, in reply, joined issue with those who deprecated interference in cases of pyo-pneumothorax. He believed that early removal of the pus by modern methods was advantageous in many cases. Good results, however, could no more be expected from a neglected pyo-pneumothorax than from a neglected empyema. He mentioned a case in which a pulmonary aneurysm caused death by rupture into the evacuated pleural cavity.

CLINICAL SOCIETY OF LONDON.

Gunshot-wound of the Eye.—Paroxysmal Tachycardia.—Fracture of the Axis Vertebra.

A MEETING of this society was held on Jan. 8th, the President, Dr. BUZZARD, being in the chair.

MR. BRUDENELL CARTER reported a case of Gunshot-wound of the Eye, in which two pellets of shot were retained and encapsuled, with preservation of sight. The patient was a boy aged fourteen years who received a charge of snipe shot in his face from a gun, the muzzle of which was only three yards away, on Dec. 14th, 1895. Most of the charge entered the mouth and the jaws were much injured, but two pellets passed through the left lower lid and entered the eye, piercing the sclera below the cornea, one just to the nasal side of the vertical meridian, the other on the same horizontal line and four or five millimetres nearer the nose. Mr. Carter saw the case two days after the accident, and after dilating the pupil was able to see that the retina had been wounded. An expectant treatment was pursued, and the eye recovered without inflammation or trouble of any sort. He thought the pellets had been sterilised by heat and possibly cleansed by passing through the lower eyelid. By Feb. 4th, 1896, all the blood effused within the eye had been absorbed; and it was then seen that the retina and choroid, having been wounded below the optic disc, had disappeared from an extensive region, probably by retraction, leaving the internal surface of the sclera exposed to view, while on the temporal margin of the gap thus occasioned two pellets of shot were lodged and encapsuled, one slightly above the other, producing elevations which were about a millimetre above the general level of the fundus. Central vision is now equal to $\frac{1}{12}$ths of the normal, and the gap in the upper part of the field is too remote from the fixing point to occasion any inconvenience. Since the accident the boy has passed into a public school, and he now takes part in all the games and pursuits suitable to his age and position.—Dr. KINGSTON FOWLER asked what Mr. Carter would regard as indications for expectant treatment. He had an impression that excision was too hastily decided on in these accidents, which were not uncommon among sportsmen.—Mr. MAKINS asked if there was any danger of the retained pellets setting up mischief.—Mr. R. J. PYE-SMITH asked if any accurate investigations had been made as to the actual temperature of shot.—The PRESIDENT remarked on the many points of interest raised by the paper and asked to what extent passage through the skin could be relied on to make an object aseptic.—Mr. BRUDENELL CARTER, in reply, said that as a matter of experience heated missiles always acted as sterile bodies when they injured the eye. He did not know of any precise observations as to their temperature. He quoted several cases in which heated pieces of metal had penetrated the lens and remained there without exciting inflammation. He thought it was always safe to pursue expectant treatment for about three weeks, as sympathetic ophthalmia rarely occurred before that time. If the macular region were injured there would be no object in waiting and he would advise the performance of Mules's operation.

Dr. W. P. HERRINGHAM read a paper on a case of Paroxysmal Tachycardia in a girl aged eleven years. The child was under observation from September, 1895, when she was eleven years old, to June, 1896, during which time she had seven attacks of tachycardia. The history showed that she had been subject to similar attacks for at least five years. The attacks were typical in character. They began quite suddenly in a period of perfect health and without adequate cause. The beginning was never witnessed by Dr. Herringham. They lasted for a period which varied from thirty-six hours to thirteen days, and the end of the paroxysm took place during sleep. During the attack the pulse was very small and soft, uncountable at the wrist, of a rate which, taken at the heart, was from 240 to 260; the heart was somewhat dilated beyond its usual size, and the pulsation was very forcible. It was at first productive of some præcordial distress, but not of acute pain. Respiration was rapid and there was occasionally a little cyanosis, but no sign of pulmonary œdema. There was no anasarca of the legs. The urine during the attacks was very scanty, owing doubtless to the low blood pressure. During the paroxysms sleep was restless and did not alter the cardiac rate. Since they ended during the night the actual moment of change was never witnessed, and it could not, therefore, be told whether this was instantaneous or a matter of hours. The pulse, which had been over 200 the night before, was found in the morning to be 90 or thereabouts and the child professed herself quite well. The causes which excited the attack appeared to be either sudden effort or sudden movement, yet neither of a degree likely to produce any ill effect upon ordinary persons. No valvular disease could be detected nor was there any history of rheumatism in the child or in her family. There

Hosted by Google

was no sign or history of syphilis and the patient between the attacks was a big, plump, rosy girl the picture of health. The heart, however, is permanently enlarged and Dr. Herringham suggested that there might be adherent pericardium and that the myocardium itself might, as the result of some former disease, be unhealthy. From a study of the literature of the subject and from watching the present case he was disinclined to believe that these hearts were structurally healthy and he thought that the change in them might originate in three ways. In some cases it might be due to acute myocarditis, as in those which had been seen in rheumatic people; in others it might be due to degeneration of the muscle itself, either syphilitic, as probably in two of the recorded necropsies, or fibrosis; and that again in a third class it might be primarily due to nerve degeneration, as in some cases noted after infectious fevers. Various modes of treatment adopted—digitalis, nitrite of amyl, atropine in large doses, pressure upon the vagus nerve, treatment directed to the stomach and intestines—had all proved useless, or if any drug had at one time seemed to cure it failed to repeat the performance. The Schott treatment by baths and exercises neither reduced the size of the heart nor prevented the occurrence of the paroxysm.—Dr. ABRAHAMS thought these cases were of nervous origin and that the attacks were analogous to the respiratory spasm in whooping-cough.—Dr. SAMUEL WEST remarked on the rarity of the disease in children. He had never been able to find any adequate explanation for the paroxysms. He did not agree with those who said that the patients were otherwise healthy. There was in almost all dilatation of the heart. This complaint did not necessarily interfere with work, as illustrated by the case of a policeman who was able to remain on duty. During his attack murmurs developed, loudest at the base, which were distinctly audible a couple of feet from the patient.—Dr. SEYMOUR TAYLOR had seen six cases in adults, two of whom died a few years later from disease of the abdominal viscera, which suggested that the paroxysms might be brought about through the sympathetic. If they were of central origin he would regard them as analogous to epileptic paroxysms rather than to those of whooping-cough, as the patients in the intervals were perfectly well.—Dr. GLOVER thought that arsenic and strychnia were most likely to be beneficial. Had they been tried?—Dr. C. W. CHAPMAN recommended the use of a combination of bromide of ammonium with arsenic.—Dr. KINGSTON FOWLER quoted Dr. Sharkey as having obtained good results with increasing doses of valerianate of zinc, beginning with three-grain doses.—Dr. LUCAS BENHAM had used opium with advantage.—Dr. HERRINGHAM, in reply, said that although the theory of a nervous origin was plausible and tempting there was no proof of it. In three of the six necropsies definite structural change in the heart was found. Compression of the thorax had been employed by Rosenfeld with success, but he had not yet had an opportunity of employing it in the present case.

Mr. CUTHBERT S. WALLACE described a case of Fracture of the Axis Vertebra. The patient, a man aged forty-four years, fell a distance of nine feet and was carried up to bed while unconscious. On the next day the patient sought advice because of the rigidity of his neck. On examination it was seen that the head was protruded and the chin almost touched the sternum. A slight projection was felt in the cervical spine on examining the posterior wall of the pharynx, but this was not tender. The patient was laid on a flat bed and the head fixed with sand-bags. Rigidity passed away and good movement returned by the eighth day; on the afternoon of this day the patient was suddenly seized with dyspnœa and died. Post mortem a fracture of the axis was found that separated the two superior articular parts with the odontoid process from the inferior part of the body. No injury of the cervical cord was found.

OBSTETRICAL SOCIETY OF LONDON.

The Etiology of Eclampsia.—Breech Presentation with Extended Legs.—Exhibition of Specimens.

A MEETING of this society was held on Jan. 6th, the President, Dr. F. H. CHAMPNEYS, being in the chair.

Dr. MACNAUGHTON JONES read a note on the Etiology of Eclampsia. After referring to the well-known theories of the causation of this disease he proceeded to relate an instance in which induction of abortion was necessary for albuminuria. The patient had well-marked eye symptoms, much sickness, and headache. After abortion took place further fits occurred, followed by coma. He had administered two subcutaneous injections of pilocarpine. The patient recovered.—Dr. JOHN PHILLIPS, while agreeing with the treatment adopted in inducing abortion, considered that the use of pilocarpine was attended with grave danger. He called attention to his paper on the Value of Pilocarpine in Pregnancy, Labour, and the Lying-in,[1] in which the whole subject had been carefully considered, and thirty-nine cases in which pilocarpine had been used in convulsions reported. In nine of these cases dangerous symptoms followed shortly after the exhibition of the drug and seven died. His experiments showed that rapid œdema of the lungs took place sometimes within a few minutes of the injection, and he ventured again to warn his fellow practitioners against its use.—Dr. HERMAN said that pilocarpine was a dangerous drug in puerperal eclampsia; it made the skin sweat, but it also made the bronchial tubes sweat. One of the dangers of this disease was the liability to pulmonary œdema and inflammation after the fits had ceased, and this danger was increased by the use of pilocarpine. He approved the induction of abortion in this case, and to it and not to the pilocarpine he attributed the good result.

Dr. W. S. A. GRIFFITH and Dr. A. W. W. LEA read a paper on Breech Presentation with Extended Legs. This paper was the result of seventeen cases, which were briefly described, and the following conclusions were arrived at:—1. The extension of the legs in incomplete breech presentations may be either primary or secondary. 2. In the primary variety, which occurs before labour has begun, the breech engages readily in the brim and the diagnosis can be made. 3. In the secondary variety the extension occurs during labour. This form is more frequent than the primary. 4. This complication is more frequent in primiparæ—viz., 70 per cent. of the cases. 5. The prognosis with regard to the child is not worse than is that in pelvic presentations in general. 6. Cephalic version is advantageous before labour is advanced. It is not usually possible in the primary, but may be so in the secondary variety. 7. Most cases are delivered naturally. 8. Prophylactic reduction of the leg is only required in exceptional cases. 9. It is probable that flexion of the leg on the thigh is preferable to pulling down the leg into the vagina. 10. If aid is required in the lower part of the pelvis the soft fillet will usually effect delivery.—Dr. AMAND ROUTH congratulated Dr. Griffith and Dr. Lea on their very valuable paper. He doubted very much if their statement that the prognosis as regards the child was no worse when the legs were extended than in ordinary breech cases was correct. This might be so in a hospital, where an exact diagnosis would be made early in labour, but in general practice he believed the result was very different. He had seen cases where a correct diagnosis of the cause of the delay had not been made and others where a diagnosis had been made but efforts to bring down the legs had failed. He also thought that prolapse of the cord in breech cases was not so serious as had been stated in the paper.—Dr. C. HUBERT ROBERTS asked Dr. Griffiths and Dr. Lea if they could explain the cause of the curious primary extension of the legs in these cases, as nothing had been written at present on the matter. With reference to the cases, Dr. Roberts thought that the question of diagnosis was very important, and if this were always possible and certain (because it was evident that interference was necessary in such cases) the question arose, When ought they to interfere? Dr. Roberts congratulated Dr. Griffith and Dr. Lea on the small mortality of their cases. With regard to the children he had been led to believe that the mortality was very much greater. He considered that the use of the forceps was dangerous treatment.—Dr. SPENCER did not think that primary extension of the legs could be diagnosed from the fact that they assumed that position after birth. The great majority of children tended to extend the legs after a difficult birth in that position, but he did not think it proved that the limbs had occupied this position before labour. The child presenting by the breech was known not infrequently to lie with the legs stretched out towards various parts of the uterus, but he did not think the feet were forced up to the shoulders till labour occurred

[1] Transactions of the Obstetrical Society, vol. xxx., p. 354.

Hosted by Google

except in the rare cases of *genu recurvatum*, in which, however, the joint was not ankylosed, as he understood Dr. Griffith and Dr. Lea to state, but subluxated.—After remarks from Dr. BOXALL the PRESIDENT said that he had seen a case of primary extension of the legs with vertex presentation lead to difficult delivery. A patient with a normal pelvis and a small child fell in labour which could not be terminated by natural efforts. On examination a presentation of the vertex in the first position was found together with presentation of the left arm and the left foot. He suspected twins and thought that the foot at least was contributed by a second fœtus. The child was delivered by forceps and no twin was present. The legs after birth lay on each side of the neck. The newness of the subject might be illustrated by the fact that so careful and learned an observer as the late Dr. Matthews Duncan told him that he had never seen a case of primary extension of the legs. As to the question when to interfere, interference should always be resorted to when in a case of breech presentation delay took place at any stage, even in the first stage. The paper illustrated the fact that the subject is still not thoroughly understood. It might be thought that the cases of difficulty would be those of large children, contracted pelves, and primiparæ. But, on the one hand, many large children were delivered easily, many primiparæ even with large children experienced no difficulty, and contracted pelves counted for a very small number of difficult cases. On the other hand, difficulties not infrequently occurred with normal pelves and small children. One mode of delivery was not insisted on in any book that he knew, though it might be mentioned casually, that was pressure from above. In any really difficult case where the breech was too low for the bringing down of the foot this pressure, applied judiciously and firmly by a skilled assistant, the patient being in the lithotomy position, was of the greatest service and he always used it.—Dr. LEA briefly replied.

The Reports of Committees on Dr. Remfry's and Dr. Lewers' specimens exhibited at a previous meeting were read.

The following specimens were exhibited:—

Dr. AMAND ROUTH: Case of Hysterectomy for Malignant Papilloma.

Dr. GOW: The Uterus from a case of Cæsarean Hysterectomy for Fibroids.

Dr. ARNOLD W. W. LEA: Broad Ligament Cyst with Twisted Pedicle.

Dr. C. HUBERT ROBERTS: Calcified Fibroma of the Broad Ligament, with drawings and microscopic sections.

HARVEIAN SOCIETY OF LONDON.

Some Notes on Ovarian Tumours.

A MEETING of this society was held on Jan. 7th, Mr. ROUGHTON (Vice-President) being in the chair.

Dr. W. J. GOW read a paper on Some Notes on Ovarian Tumours, his remarks being mainly founded on a series of forty-seven cases in which he had performed ovariotomy. He dealt first with the symptoms of ovarian tumours, and after alluding to the frequent absence of any symptoms other than those of progressive abdominal enlargement he showed that disturbances of menstruation and pain were comparatively common. Menorrhagia and metrorrhagia were more often met with than amenorrhœa. He alluded also to procidentia uteri as a condition which was sometimes associated with the presence of an ovarian tumour, and stated that in six cases of complete procidentia in young virgins which had come under his notice three of them were complicated by tumours of the ovary, and therefore it seemed probable that in young unmarried girls there was some distinct causal relation between the development of ovarian new growths and the occurrence of procidentia. He also discussed briefly the etiology of suppurative changes in ovarian cysts, and the symptoms of rupture, as well as certain difficulties in the differential diagnosis of ovarian tumours from pregnancy and uterine fibroids. He described a case in which he had performed ovariotomy on a patient who was the subject of diabetes mellitus. He stated that among his forty-seven cases there was no mortality, and concluded by briefly alluding to certain important points relating to the operation of ovariotomy.

Mr. ALBAN DORAN never trusted to menstrual disturbance as diagnostic of ovarian tumour. Amenorrhœa was usual in sarcoma of the ovary. Menorrhagia was possibly due to shortness of the pedicle irritating the uterus. Violent attacks of pain were not rare in cases of ovarian cyst where no adhesions or torsion of the pedicle could be found at the operation. Perhaps the pain was caused by temporary torsion. Mr. Doran was still in favour of short incisions, but diagnosis sometimes required a large wound, else the operator's fingers might do damage in the dark, and when the incision was too small the tissues of the wound got badly bruised and a weak scar was the result. Ligature of the pedicle in several sections was not advisable. Even in a very broad pedicle, when the outer and inner borders were secured separately, a single transfixion was sufficient. Penrose even omitted the transfixion in oöphorectomy, and believed that the tying of the vessels in the borders was sufficient in ovariotomy. The outer border should always be tied separately. Double transfixions were sometimes followed by suppuration around the ligatures.

Dr. BOXALL remarked on the difficulties of diagnosis occasionally met with and endorsed the advice given by Dr. Gow to be always prepared for hysterectomy even in what appeared the most straightforward case.

The CHAIRMAN, Mr. DUTCH, Mr. JACKSON CLARKE, and Dr. CORK joined in the discussion and Dr. GOW replied.

NEUROLOGICAL SOCIETY.

Presidential Address on Heredity in Neurosis.

A MEETING of this society was held on Thursday, Jan. 14th, in the rooms of the Medical Society, when Dr. G. H. Savage delivered his Presidential address.

Before commencing his paper he referred to the death of Dr. Hack Tuke, which had placed him as representative of the Psychiatric Branch of the society. He considered first heredity and the present ideas in relationship to it, next the meaning of the terms "neurosis" and "neurotic," then he traced the relationship between the various neuroses, and pointed out how they were related to neuroses in the parents. He then discussed the special liability of the insane neuroses to recur and gave his explanation why certain insanities were more likely to be transmitted than others. To go more into detail Dr. Savage began by tracing the ideas of heredity from the Darwinian to the Weismann period. He could not admit that there was no power of transmitting acquired capacities. He felt that great misunderstanding had arisen from the idea of the direct transmission of fully developed habits or faculties, whereas all that was transmitted was a capacity or predisposition for developing these habits. He said that the very existence of species which bred true and yet were seen to be related with other species was proof of a power to vary and a power slowly to acquire even specific characteristics. Time prevented man from watching such processes. The transmission as far as man was concerned was seen, not in increased mass of nervous tissues, but in increased adaptability of the tissues and organs already existing, and this power to develop in adaptability allowed increased power of going wrong—that is, not fitting into the developing surroundings. There is a fair comparison between the nucleus which clothes itself with germinal matter and the individual mass of germ plasm which clothes itself with an appropriate soma which is suited to the future needs of the animal. The transmission of the simpler parts and the simpler instincts are allowed to take place, and it is only from their complexity that the more elaborate cannot equally be traced and investigated. In the transmission of instincts it was shown how some were transmitted but were perhaps never developed—that, in fact, there may be potential abilities which are never evoked because no stimulus has been present. It is thus, too, with some neuroses which seem to lie dormant till special conditions give rise to their appearance. Later Dr. Savage referred to cases in which tendencies to special forms of mental disorder only occurred at certain ages. Neurosis was defined as the morbid instability which caused most of the bodily disturbances to be represented too rapidly or in too great a degree along the nervous lines—that is, the undue nervous expression of bodily states. He showed that this might, in fact, generally did, depend on causes of physical weakness in the progenitor or in the individual, and he

Hosted by Google

pointed out how often similar states of nervous instability and of disorder resulted from either previous disease of a similar kind in the parent, or in the patient, at an earlier period of life. All neuroses are not to be considered as insanities, and some of the most confirmed neuroses never pass into insanity. It is thus with true hypochondriasis. The relation of heredity to the neuroses has to be traced in various ways, one of the best being the consideration of the nervous disorders which commonly occur in the offspring of the insane and markedly neurotic. These consist of defect of nerve power of various degrees shown by defect of one or other of the mental factors, which may give rise to various forms of idiocy, or lesser degrees of defect which may give rise to smaller degrees of mental weakness. Then there is marked want of stability, which gives rise to irregular development—onesidedness, which may be seen in idiots, savants, and in some prodigies; in impulsive acts, which are in many cases exaggerated reflexes; convulsive attacks, which are readily started in the neurotic child and may lead to habitual convulsions (epilepsy) or to permanent mental weakness; defective control leads to various other symptoms in the neurotic, such as somnambulism, wetting of bed, sexual precocity, &c. Due to similar causes are some forms of mimicry with peculiar forms of morbid expression, such as stammering, grimacing, and the like. Next in the neurotic there is a special tendency to irregular rises in temperature in childhood, and with this there is special danger of severe and easily started delirium. Other connecting links in the neurotic chain were given and then Dr. Savage pointed out that it was of interest to note how the same nervous symptoms might occur in patients who had insane parents and in those who in youth had had attacks of insanity themselves. This was well seen in some cases of so-called moral insanity. The children of some insane or highly neurotic persons had either no recollection of punishment or else were unable to associate certain acts with certain pains; in some cases the criminal acts were simply uncontrolled impulses pending on original nervous weakness. Lying of different kinds was described both as occurring alone and associated with thieving. Cruelty, the uncontrolled exercise of power in some cases and in others a mere uncontrolled reflex, and precocious sexuality, with its varieties and possible causes, were referred to. The next part of the subject was on the relationship of the various forms of insanity to heredity. Dr. Savage pointed out that ordinary mania was not a form of neurosis which bred true, that it did not seem to have a sufficiently definite physical basis for it to be transmissible, but there was the form of acute delirious mania which was interestingly allied to the early delirium in childhood which was easily evoked in neurotic subjects and was a very grave disease. Melancholia, on the other hand, being specially associated with general bodily ailment, was a disorder which was often met with in generation after generation in certain families. Thus certain families tended to die out in mind before body, in some the individuals living to extreme old age, and in some of the nervously unstable there seem to be capacity for passing on a tendency to recurring melancholia, which in the end became chronic. Dementia in a similar way was often associated with the old age of certain families. The way in which the mental decay occurred generally followed the same lines in members of the same family. The next point in the part of this subject was the relationship of systematised delusional insanities to heredity. It was pointed out that in nearly all these cases there was either neurotic heredity or a history of previous attacks of insanity in the individual. The occurrence of similar imperative ideas in parent and child was referred to and explained as possibly only like the recurrence of muscular tricks under similar conditions. The various monomanias were spoken of and the relationship which exists between heredity and general paralysis of the insane. It was said that in general paralysis the neurotic heredity was not often strongly marked, but that if it occurred it seemed to affect the course of the disease, in some cases leading to frequent remissions and in others to a chronic course in the disease. It was suggested that where there was a history of syphilis and heredity locomotor ataxy was not uncommon, while under similar conditions without the heredity general paralysis was more common. What in some cases looks like direct heredity is, after all, the result of nervous instability associated with dread and expectancy; this is well seen in some cases of puerperal insanity and the suicidal tendency recurring in certain families. Heredity is an important factor in the production of neuroses; it is an important element, too, in their transmission, but the transmission depends as much on the stimulus which evokes the symptoms as on the heredity, and it is this which is so important for the consideration of the physician. There is no absolute tyranny of the organisation any more than there is tyranny of the surrounding. There is, therefore, hope in changing the surrounding of the neurotic and thus breaking morbid habit or preventing its development. There are no specific differences between the neuroses; they are links in the same chain. There is evidence that acquired neuroses will lead to a changed condition in the offspring, so that it was not true, in his opinion, that nervous acquisitions or defects cannot be transmitted.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

Transplantation.—Retarded Eruption.—Methods of Preventing Deformity after Removal of Portions of the Mandible.

THE ordinary monthly meeting of this society was held on Jan. 11th, Mr. R. H. WOODHOUSE, President, in the chair.

Mr. H. L. ALBERT read a communication on two cases of Transplantation, with a third case of transplantation of a root subsequently crowned. He referred in detail to the three cases and then explained the method of procedure he usually adopted, which was as follows. A tooth was first selected of suitable colour and shape with a root slightly wider than the one to be removed; the tooth was then denuded of its periosteum and any deposits which might be attached to it. The apex of the root was then cut off and the pulp chamber sterilised and filled. The tooth to be removed was grasped at its neck and as much rotation as possible employed in its extraction in order to avoid deflecting the alveolus. The socket was then washed out with an antiseptic, and the tooth to be transplanted forcibly pushed into position, care being taken that the bite was clear. He laid stress upon the avoidance of ligatures and splints, as they were, he thought, only traps for bacteria and therefore likely to lead to periosteal trouble.

Mr. E. BALDING recorded a case of Retarded Eruption in a girl aged eleven years and eight months. All the milk teeth were present with the exception of the left upper and lower second molars and the right upper central, the latter having been shed consequent on the eruption of its permanent successor; the four first permanent molars were also erupted, but beyond this there were no signs of any permanent teeth.

Mr. A. PEARCE GOULD read a paper on Methods of Preventing Deformity after Removal of Portions of the Mandible. He first of all referred to the fact that the surgery of the lower maxilla differed materially from that of the upper, for while removal of a large portion of the upper maxilla would leave only a trifling deformity removal of a large portion of the mandible caused considerable external deformity as well as great interference with its function in mastication. He stated that comparatively little effort had been made to deal with this question and referred at some length to the attempts made by Liston and Fergusson in former days and by Boyd and Stokes in recent times. He then related in detail three cases which had come under his care and in which he had endeavoured to overcome the deformity resulting from removal of portions of the mandible. The first was a case of recurrent epithelioma in a man aged fifty-two years. He removed a considerable part of the left half of the mandible and between the extremities of the remaining portion he inserted a stout silver wire. As long as the man remained in hospital the result was excellent, but during his stay in a convalescent home the wire became shifted and appeared through an aperture in the cheek, the patient removing the wire himself. The second case was one of epithelioma of the gums on the right side. A piece of the mandible, about two and a half inches long, was removed, and between the extremities of the remaining portion a stout steel bar was inserted by means of screws turning in different directions. The skin and mucous membrane were then stitched over the rod. The result was excellent. The external deformity was but slight and the

Hosted by Google

mandible moved in one piece. The third case was one of recurrent epithelioma involving the floor of the mouth and the greater part of the tongue, as well as the neighbouring lymphatic glands. A portion of the mandible from canine to canine was removed, in addition to a large amount of the adjacent soft tissues. A steel bar with reverse screws at the ends was inserted, but after a few days the right end became loose and was replaced. A few days subsequent to this the left end became dislodged and was found to have slipped right into the left half of the mandible. The steel bar was accordingly removed. In commenting upon his three cases Mr. Gould remarked that what they wanted was something rigid, yet easily adaptable, and he thought that the best method to adopt was a question for the future to decide.—Mr. STANLEY BOYD stated that in one case he had operated upon he simply put a knitting-needle between the extremities of the remaining portion of the mandible, fixing one end of the needle into the dental canal, and the other end into a hole drilled in the bone. The needle, however, became displaced. He thought, with Mr. Gould, that the material to be used must be easily adaptable, and he knew of nothing better than polished steel. It was strong, could be broken if desired, was non-absorbent, and in his experience did not rust. To prevent displacement it was needful for the extremities of the bar of the material used to have a shoulder. A point of importance was in his opinion to obtain speedy union, for as the amount of granulation tissue increased, so did the amount of contraction to be overcome.—Mr. STORER BENNETT, Mr. CUNNINGHAM, Mr. DENISON PEDLEY, Mr. REDMAN, Mr. LLOYD-WILLIAMS, Mr. COLYER, Mr. NEWLAND-PEDLEY, and Mr. BALDWIN also took part in the discussion.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A Plea for a more Precise Classification of Disease.—Six Cases of Strangulated Hernia in Infancy and Early Childhood.

A MEETING of this society was held on Jan. 8th, Mr. W. BRUCE CLARKE, President, being in the chair.

Dr. W. J. TYSON (Folkestone), read a paper entitled "A Plea for a more Precise Classification of Disease." He pointed out that with increasing knowledge many causes of disease hitherto classed as "predisposing" or "exciting" must give place to others more precise. He criticised the frequency with which cold or chill is alleged as a cause of disease and showed how recent advances in bacteriology had furnished proof of the real causation. He urged that the known causes of diseases should have a proportionate value put upon them, and that no prominent symptoms should be classed as a disease if it be possible to put a causative or defining adjective in front of it. He illustrated his contention by referring to three diseases—viz., pneumonia, peritonitis, and meningitis. —Dr. TRAVERS agreed with the remarks made in the paper. He thought it would be better to differentiate more carefully the type of a disease such as pneumonia.—Remarks were also made by Mr. LLOYD and Dr. THUDICHUM.—Dr. TYSON, in reply, said that the main object he had in view in presenting the paper was to try to differentiate clinically many of the diseases which were placed under the title of one word, and under this word were included many diseases which in their symptoms, prognosis, and treatment were clinically distinct. The subject was an important one practically, for the treatment of the disease could not be satisfactorily carried out until the form or the variety of the disease had been determined.

Mr. STEPHEN PAGET read a paper on Six Cases of Strangulated Hernia in Infancy and Early Childhood. The six cases all occurred in male children; three of them were three months old, one seven months, one a year, and one between two and three years. All were examples of inguinal hernia, five being on the right side and one on the left. In three of the six cases the cæcum was in the sac. Two of the infants died, and in one case the wound broke down after the operation. The cases were described in detail.—Mr. KEETLEY said that the escape of intestines through the wound and beneath the dressings in the case of infants operated on for hernia has not been a very uncommon accident. It is one not likely to have been always reported. He advocated careful suturing of the wound in layers as an effectual means of preventing the accident. He formulated the following rules:—(1) Operate from the front with the full intention of doing a radical cure; (2) cut straight down upon the neck of the sac, open it and the peritoneal cavity at the same time; and (3) after returning the bowel separate the sac high up from the cord, tie it there, and then sew up the hernial opening so tightly that it will only first permit (if the child be a male) the cord to pass through. The child should be kept warm with cotton-wool and hot cushions. The amount of anæsthetic given should be reduced to a minimum.—Mr. MCADAM ECCLES remarked that he did not consider strangulation of congenital inguinal hernia in male infants uncommon, but that operation for such was a rare necessity, unless there was evidence of gangrene or part of the contents was irreducible. Inversion of the patient would usually lead to reduction of the contents. He alluded to the occurrence of the cæcum in the sac as the outcome of its being dragged by the gubernaculum behind a patent processus vaginalis. This might become the seat of inflammation rather than strangulation.—Dr. MCCANN referred to his experience of strangulated hernia at the Hospital for Sick Children, Great Ormond-street. He firmly believed that very few cases ever required operation, as he had seen well-marked examples completely recover after suspension of the child. He was strongly opposed to repeated taxis, whether under an anæsthetic or not, as the taxis was an important cause of gangrene of the bowel. The suspension or inversion of the child should be resorted to at once before any attempts at taxis were made. He thought intestinal distension from improper feeding an important cause of hernia and strangulation.—The PRESIDENT remarked that he thought the reason why the difficulty of reduction of these cases of strangulated hernia on the right side in male infants occurred was a condition which was well shown in one of Mr. Paget's specimens. The testicle was adherent to the cæcum, having acquired this adhesion probably *in utero*. In one or two adults on whom he had operated, and also in one case of a child, this condition was very obvious, and no sooner was the connexion severed than the difficulty in reduction vanished. In two such instances he had found it necessary to remove the testicle, which, he might remark, was atrophied and presumably useless.—Mr. PAGET, in reply, urged that an early operation avoided the danger of returning gangrenous bowel, several instances of this disaster being on record.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

The Method of Serum Diagnosis in Typhoid Fever.—Exhibition of Cases and Specimens.

A CLINICAL and pathological meeting of this society was held on Jan. 6th, Dr. W. B. RANSOM, President, being in the chair.

The PRESIDENT dmonstrated the Method of Serum Diagnosis in Typhoid Fever. He had used an emulsion of a gelatin culture of typhoid fever bacilli, a peptone bouillon culture, and a culture of human ascitic fluid. The blood was drawn from the ear either into a sterilised pipette or small sterilised bottle, or allowed to form a dry clot on glazed paper, a drop of water being added to the clot when the test was applied. In a case of tuberculous meningitis and one of diabetes no agglutinative action was obtained, and the bacilli moved freely without clump formation in the ascitic fluid until typhoid fever serum was added to it. Four cases of typhoid fever had been tested: 1. A man in the third week (severe case; temperature 104° F.) gave clumps in five minutes. 2. A man in the third week (mild case; temperature 101°) gave clumps in twenty minutes. 3. A woman in the third week (mild case; temperature 100°) gave clumps in thirty minutes; on the twenty-sixth day, her temperature being 99°, clumps occurred slightly in one hour. 4. A woman on the thirty-fifth day (fairly severe case; temperature 100°) gave clumps in thirty minutes; on the forty-second day no clumps were obtained.

The PRESIDENT showed a woman aged thirty years, single, the subject of Acromegaly. For seven years she had had constant headache, amenorrhœa, gradually increasing weakness, and loss of visual power, with enlargement of the extremities and face. There was bi-temporal hemianopia,

Hosted by Google

and in the right eye considerable contraction also of the nasal field. Vision was $\frac{6}{9}$ in the nasal field of the left eye, and $\frac{6}{24}$ in the nasal field of the right eye. The optic discs showed atrophic changes. There was no glycosuria. The thyroid gland was not enlarged. Treatment had failed to arrest the disease, though a free purge relieved the headache for a time.—The PRESIDENT also showed the organs removed from a patient, a case of Acromegaly,[1] who died from coma in October, 1896. The pituitary body was much enlarged, being three and a half inches by one and a half inches in size, and formed a soft, friable, vascular tumour which excavated the sella turcica and formed a large depression in the lower surface of both frontal lobes. The gland tissue appeared to be entirely replaced by an angio-glioma. The thyroid gland was enlarged and showed microscopically simple hypertrophy. The liver contained an angioma which had a fibrous stroma and in which a few cells like those of the pituitary tumour were found. In this case there were glycosuria and marked bi-temporal hemianopia. The optic nerves were much flattened.

The PRESIDENT also showed the Stomach and Liver of a man who in life had symptoms somewhat resembling Pernicious Anæmia. There was a large carcinomatous ulcer in the stomach infiltrating both liver and pancreas, shreds of which organs were found in the gastric cavity. The patient had been ill a year, vomiting only at the commencement, and during his stay in hospital for the last month of his life showing no gastric symptoms. There was irregular pyrexia, moderate loss of flesh, lemon-yellow skin, and extreme anæmia. Red corpuscles equalled 30 per cent., hæmoglobin equalled 20 per cent., and there were a few poikilocytes. When first observed the leucocytes were not increased, but a week before death there was one leucocyte to fifty red corpuscles. The increase was entirely due to the polynuclear or finely granular oxyphile cells, no eosinophilous and myelocytes being found. At the necropsy the medulla of the tibia was of the normal pale yellow colour.

Mr. CHICKEN showed Two Urinary Calculi. The first, which weighed 1700 grains, was removed by suprapubic lithotomy. The second, which weighed 1075 grains, was treated by litholapaxy, the operation occupying one and a half hours.

Mr. SMITH showed:—(1) The Organs from a case of Hydatids in the Liver and Lungs; (2) a Malignant Growth causing Intussusception; (3) the Intestine from a fatal case of Obstruction caused by a constriction formed by a thickened and contracted mesentery; and (4) an unusual form of Supernumerary Toe.

Mr. WILLIAMS showed a specimen of Tubal Gestation with the Fœtus *in situ* which he had operated on and removed before rupture occurred.

Mr. TRESIDDER showed Microscopic Specimens from a case of Epithelioma of the Rectum occurring in a girl aged seventeen years. The symptoms had lasted one year.

LIVERPOOL MEDICAL INSTITUTION.

President's Address.

A MEETING of this society was held on Jan. 7th, Dr. RICHARD CATON, President, being in the chair.

The following vote of congratulation to Sir Joseph Lister, proposed by the President and seconded by the Senior Vice-president, was passed with acclamation:—

"The members of the Liverpool Medical Institution beg to congratulate Sir Joseph Lister on his approaching elevation to the Peerage, and desire also to express their satisfaction that the medical profession is gaining in him so esteemed and distinguished a representative in the upper chamber of the legislature."

The PRESIDENT then gave his inaugural address on the Results of Recent Excavations at Epidaurus and Athens bearing on Medical Treatment in the Temple of Asklepios. After referring to the existence of hospitals and of a medical cult in Egypt as early as 3500 B.C., as proved by the reseaches of De Morgan, the President described the Asklepian sanctuary at Hieron near Epidaurus, the temples, the abaton or sleeping portico for the sick, the tholos, the baths, library, theatre, stadium, and grove. He also gave a description of the smaller temple of Asklepios at Athens and a summary of the more important points contained in the 300 inscriptions recovered at Hieron and Athens narrating some of the miracles attributed to the god; also details of medical treatment. The address was illustrated by fifty lantern slides, representing the existing remains and also restorations of the shrines.

After the address the President entertained the members at a smoking concert.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Widal's Method of Diagnosing Enteric Fever.—Concurrent Scarlet Fever and Enteric Fever.

A MEETING of this section was held on Dec. 18th, 1896, Dr. G. F. DUFFEY, President, being in the chair.

Dr. MCWEENEY gave a demonstration of Widal's Method of Diagnosing Enteric Fever. The apparatus he used was a Pasteur pipette consisting of two wide parts separated by a very narrow one. The end intended for aspiration was plugged with cotton wool and the other end was drawn out to a fine capillary point and the whole pipette sterilised. He generally sterilised the finger of the patient from which the blood was to be drawn. The skin was pricked with a lancet needle, and the drawn-out end of the pipette, after the extremity was snapped off with sterilised forceps, was introduced into the drop of blood. A sufficient amount to fill the tube was easily obtained by pressure and aspiration and then both ends of the tube were sealed by fusion. Conditions necessary for success in the diagnosis were that the bacterial cultivations should be pure, typical, and young, the most important characteristic being motility of the bacilli. When serum taken from a typhoid fever patient was added to such a cultivation an almost instantaneous agglutination was seen under the microscope, large masses of bacilli becoming stuck together in masses in which the outlines of the individual bacilli were hardly distinguishable. In some cases all the bacilli appeared to be massed together. In other cases of equally undoubted typhoid fever type a considerable number of individual bacilli—even a large minority—remained pursuing their motions between the agglomerated masses. They seemed to be attracted by some force, as it were, to the massed collections. If the serum was not that of a typhoid fever patient the bacilli moved about amongst the blood corpuscles and a swaying movement of the latter could be seen, occasioned by their contact with the bacilli. The blood of the typhoid fever patients agglutinated and paralysed the bacilli, and the blood of the non-typhoid fever patients did not. Dr. Johnston of Montreal adopted a different process in applying the test—viz., by taking the drop of blood on a sheet of sterilised paper and afterwards dissolving the scrapings of the drop in water, which he then tested. It might be alleged that the blood of persons not suffering from typhoid fever might cause the bacilli to be agglomerated; but he had made the experiment with the blood of as many diseases as possible—scarlet fever, pneumonia before and after the crisis, synovitis, phthisis, and a number of other diseases—and had placed blood from them in contact with typhoid fever bacilli, and the typhoid fever bacilli exhibited no alteration in their motility. It might also be objected that bacilli which were not typhoid might become agglutinated if mingled with the serum of a typhoid fever patient. But he had found that non-typhoid organisms having active motility exhibited no alteration whatever in their movements when brought into contact with typhoid serum. — Dr. COLEMAN said that he tested the blood of eleven typhoid fever patients on twenty different occasions and in every case there was immediate "clumping" of the bacilli with loss of motility. In one case a few bacilli remained motile for five minutes, though the clumping was very obvious. The age of the patients varied from nine to thirty years and the cases from mild to severe, whilst the dates of their illness included from the beginning of the second week to advanced convalescence. One patient gave the reaction although the temperature had been normal for eighteen days. He tested the blood of three healthy persons, and also that of persons suffering from acute croupous pneumonia, rheumatic fever, gonorrhœal synovitis, measles, scarlet fever, and phthisis, and in none of these cases did the bacilli lose their motion or become agglomerated. The method which he adopted in the greater number of cases was to obtain a drop of blood from the patient's finger, to touch the blood with a clean cover-glass, and then with a

Hosted by Google

sterilised platinum loop to convey a few drops of the broth culture to the cover-glass, to mix the blood and the culture on the cover-glass with the platinum loop, and to examine immediately under a high power. In that way it was possible to examine three or four cases in a quarter of an hour in the hospital ward.—Dr. DEMPSEY said he had been concerned in the trial of this method in eighteen cases. Of these, fourteen were presumably typhoid fever, and in twelve of them there was instant re-action, and agglutinisation rapidly followed.

Dr. E. MACDOWEL COSGRAVE read a paper on Concurrent Scarlet Fever and Enteric Fever. He stated that in 1859 Murchison wrote saying that no cases had up to that time been published showing the possibility of scarlet fever and enteric fever co-existing; but some years afterwards, in his work on Fevers, he mentioned that he had seen eight cases in which the two rashes co-existed. Two of these cases he gives in detail; in each the scarlatinal eruption came out in the third week of enteric fever, most of the other cases of co-existence recorded by other observers of scarlatinal infection being taken during the progress of enteric fever. True co-existence of incubation stages has been recorded by Mr. S. A. E. Griffiths in 1893 and by Dr. Caiger, Dr. Payne, and Dr. E. Carmichael in 1894. The five cases dealt with in Dr. Cosgrave's paper were in Cork-street Fever Hospital, Dublin, in 1895 and 1896, four being under treatment at the same time. All were cases of well-marked enteric fever and all had well-marked scarlet fever followed by free general desquamation. In four of the cases the incubation stages co-existed, the scarlatinal infection being secondary to the enteric, so that the invasions were almost simultaneous, the earlier prominent symptoms being those of scarlet fever, the rose spots developing on the thirteenth, tenth, eighth, and ninth days respectively. In the fifth case the invasion of enteric fever occurred on the tenth day of scarlet fever, so that the scarlet fever infection was simultaneous with, if not earlier than, the enteric infection. The coexistence of the diseases, so far from increasing the severity of the symptoms, had rather a mitigating effect; severe scarlet fever quickly became mild, and the enteric fever, though at first severe, tended to abort at the end of the second week.—Dr. JOHN W. MOORE said he remembered seeing, with Dr. Pollock, a case of enteric fever which suddenly developed scarlatiniform symptoms, the rash being only that scarlatiniform one which sometimes developed after three weeks of typhoid fever. Very often in cases of the kind, owing to the great determination to the skin, there were destruction and shedding of the cuticle and a copious desquamation; he had seen it more than once in cases of typhoid fever.

Reviews and Notices of Books.

The Modern Treatment of Stone in the Bladder by Litholapaxy. By P. J. FREYER, M.A., M.D., M.Ch. R.U.I., Surgeon-Lieutenant-Colonel, Bengal Army (retired). Second Edition. London: Ballière, Tindall, and Cox. 1896. Pp. 120. Price 5*s*.

THE history of the treatment for the removal of stone in the bladder is probably the most interesting of any in surgery. At the beginning of this century lithotomy was the only method employed, and in this country the lateral operation was chiefly practised. The mortality was not very great when large numbers of cases are considered; for instance, according to the statistics collected by Sir Henry Thompson, there were 229 deaths amongst 1827 cases; this is equal to a death-rate of 12 per cent. for all ages, but of these there were 1028 patients who were under sixteen years of age in whom the mortality was only 6·6 per cent. This may fairly be taken to represent the condition of things up to about 1835, when Civiale's operation of lithotrity began to be employed for selected cases; a necessary consequence of this was that the mortality from the cutting operation was higher than when it was the sole method of treatment; and we find that from 1835 to 1870, during which period the two operations were about equally applied, the death-rate from lithotomy had risen to 24 per cent. (71 deaths in 290 cases), while the mortality from lithotrity was about 9 per cent. (20 deaths in 229 cases).

The later statistics of lithotrity up to 1878 show the application of the method to an increasing number of cases of stone; and by some surgeons, as Sir Henry Thompson, the method was applied to a very large proportion of the cases, and with a really low rate of mortality, amounting to less than 7 per cent., but by most surgeons, if they employed lithotrity at all, the operation was used for small stones only, under an ounce in weight, and even then only when occurring in adults in fair health.

In 1878 Bigelow introduced to the profession his operation. It was, indeed, a form of lithotrity as has been much insisted on by some English authorities, but the methods employed and the aims of the new operation were so very different that a new name was surely required for it, and though "lithotrity at one sitting" describes it fairly well, yet litholapaxy is more suitable, even if a little awkward in utterance. The complete removal of the stone at the operation itself was the most essential point in the new procedure. It must be acknowledged that at first there was in England a tendency to look askance at the new operation, and dire were the results which were prophesied would follow the introduction of the method; but as time went on litholapaxy was tried and proved to be a decided improvement on the older operation, and to-day the majority of surgeons maintain that litholapaxy is the most satisfactory method of treatment of stone in nearly all cases. The volume we are now reviewing records the personal experience of Surgeon-Lieutenant-Colonel Freyer in the employment of litholapaxy in India, by far the greatest field in the world for cases of vesical calculus. Dr. Freyer tells us that he had hesitated to try the new method, as it had been discountenanced by leading London surgeons, but he finally decided to make trial of it when he heard that good results had followed its employment in England. The book commences with a description of the lithotrites and the evacuators which are used in the operation by various surgeons. As to the lithotrite Dr. Freyer urges most strongly that non-fenestrated and partially fenestrated lithotrites should never be employed, as there is always a danger in these instruments of débris getting impacted in the jaws and thus often materially increasing the size of the instrument as it is withdrawn. This impaction can never occur with fully fenestrated instruments when properly used, for in these the male blade, when screwed home, comes flush with the hinder border of the female blade. Bigelow's handle and lock are recommended in preference to Weiss's pattern as being simpler and requiring less movement of the hands. The form of evacuator preferred by the author is one of his own designing and it certainly appears to be very simple, and we should think it would prove very effective, but the form of the evacuator is not of much importance so long as it has good suction power and so long as the current does not tend to carry back into the bladder the débris which has already been brought away. The description of the operation itself is good and full, but, as is well observed, more information will be gained by seeing the operation once well performed than by any amount of reading. Statistics come next, and we learn that since Dr. Freyer did his first lithotomy in 1877 he has operated on 864 cases of stone; of these, 244 were treated by perineal lithotomy, 6 by the supra-pubic incision, 1 by vaginal lithotomy, 3 by rapid dilatation of the urethra in females, and 610 by litholapaxy. In THE LANCET in 1885 he published full details of his first 111 cases, and this paper had undoubtedly a great influence in increasing the popularity of Bigelow's operation. At first Dr. Freyer adopted litholapaxy in selected cases only in adults, but gradually he extended it to most of the adult

Hosted by Google

cases. In 1886, influenced by the satisfactory results obtained by Brigade-Surgeon-Lieutenant-Colonel Keegan, he extended the operation to male children. At the present time he has practically abandoned lithotomy in favour of litholapaxy, as among the last 300 cases of stone he had only six lithotomies. The detailed statistics of the 610 cases of litholapaxy are of much interest. There were 439 adults, of whom 7 were women and 171 children, 6 of the latter being girls. The youngest patient was only eighteen months old, and the oldest was ninety-six years of age. The average duration of treatment was for adults six and a half days, and for children less than six days; in many cases the patient was quite well by the end of the second day. In 9 instances the disease recurred once and in 1 case twice; but in all these a long interval had elapsed between the first operation and the recurrence of the symptoms of stone, and so they were very probably all cases of true recurrence and were not due to fragments left behind from the first operation. The infrequency of recurrence in this series of cases is in striking contrast to the results which were obtained by the older method of lithotrity. Although an anæsthetic was employed in the majority of the cases, yet Dr. Freyer has on several occasions performed the operation without an anæsthetic. It is interesting to notice that kidney disease, even if severe, is considered to be no bar to the operation. Among the 610 cases, 11 deaths occurred, a mortality of only 1·8 per cent. As to the size of the stones removed 31 weighed over two ounces each and one reached the great weight of six and one-eighth ounces. Many of the stones were small, and in a few instances were evacuated by the cannula without crushing. In this connexion it is well to remember the discussion that occurred a few years ago as to what constitutes a vesical calculus when an attempt was made to fix twenty grains as the minimum weight, but it was well answered that any vesical concretion which requires operative interference for its removal is a stone. Dr. Freyer finds no difficulty in crushing many encysted calculi, though in some cases it is found necessary to crush the stone in the cyst when the mouth of the sac is too small to permit the calculus to be drawn out. The youngest child operated on was, as we have already mentioned, only eighteen months old, and this is, we believe, the youngest patient on whom litholapaxy has as yet been performed. The longest time taken in the operation was two hours, in the case mentioned above, where the stone weighed over six ounces. Many of the operations were very short, and one two-ounce stone was crushed and removed in seventeen minutes. We welcome the second edition of this little treatise and congratulate the author on his extensive and successful series of cases of litholapaxy.

A Practical Guide to Meat Inspection. By THOMAS WALLEY, M.R.C.V.S. Third Edition. Edinburgh and London: Young J. Pentland. 1896.

THE subject of meat inspection is one of such immense importance to the health of the community that a third edition of so excellent a work is thoroughly welcome. Owing to the death of the author this edition has been prepared by other hands—fortunately, by the very able ones of Professor M'Fadyean,—but no important changes have been made since the last edition. The book remains, as before, a concise but trustworthy guide to a difficult subject, the value of which is enhanced by a large number of good coloured illustrations. Full directions are given for the inspection of carcasses, with an account of the appearances presented by the flesh of animals which have died from the ordinary forms of disease or violence. No part of the book is of more importance or will be read by the medical man with more attention than the chapter dealing with tuberculosis. Here we find a very thorough account of tubercle as it affects bovine and other animals used as food, with a full appreciation of the bacteriological and experimental side of the question and a record of the various opinions which have been held as to the harmfulness of the flesh of tuberculous animals. Much difference of opinion has prevailed on this matter, but we gather, although the author does not express any dogmatic view on the subject, that he considers danger to exist even when the tuberculous lesions are localised in the viscera. There is a good chapter on ptomaine poisoning and the dangers of preserved or pickled meats. The book is a thoroughly scientific yet practical exposition of the subject, and can be heartily recommended to all who desire an acquaintance with a matter of such vital importance to sanitary science.

LIBRARY TABLE.

Roentgen Rays and Phenomena of the Anode and Cathode. By EDWARD P. THOMPSON, M.E., E.E. New York: D. Van Nostrand & Co. Price $1.50.—The author of this handy volume has gathered together all those materials which may be regarded as constituting the steps in the evolution of the x rays. It forms a complete history of the subject, beginning with Faraday's experiment in 1831 on induction and concluding with paragraphs dealing with Crookes's, Lenard's, and Roentgen's researches, and with later developments and applications of the x rays to anatomy, surgery, diagnosis, &c. The last chapter contains some excellent "skiagraphs" by Professor Goodspeed of the University of Pennsylvania. The x rays are very properly treated as part only of the subject of the radiant energy developed within, and from, a discharge tube. The plan adopted—namely, that of recording the historical experiments seriatim by means of numbered paragraphs containing cross references and sketches—renders the book admirably adapted for reference, while it affords the reader bent on further advance the opportunity of making analogy, contrast, or suggestion. The volume contains some excellent illustrations, and so far as the literature of the x rays in a collective form is concerned is the first really good contribution.

Practical Radiography. By H. SNOWDEN WARD, editor of the *Photogram*. Dawbarn and Ward, Limited, 6, Farringdon-avenue, E.C. 1896. Price 1*s*. 6*d*.—This book will be found useful by intending "radiographers" who have but a hazy practical acquaintance with electricity and photography. In short, it amounts to a popular exposition of the practical side of the subject. It is well illustrated and the directions given are trustworthy. The author has made out a simple story, and the book should afford just that assistance which those beginning the study of practical radiography would require.

Diagramettes (Hygiene). By W. H. KNIGHT, Associate of the Sanitary Institute and Member of La Société Française d'Hygiène. London: Chapman and Hall, Limited. Price 1*s*.—This is a collection of "diagramettes" reduced from twenty-four large diagrams which are designed for demonstrating the principles of sanitation. Attached to the miniature diagrams are notes on the subject and a short but clear description of the drawings. The whole range of sanitary science is thus included, the series concluding with illustrated articles on disinfection, clothing, and foods. The subject is ably treated and the descriptions and recommendations appear to be trustworthy. The illustrations are decidedly good and should do excellent service in conveying an accurate idea of efficient sanitary construction. The author is to be congratulated on having included with no apparent sacrifice of detail practically every branch of the subject. With these drawings and explanatory details before him the student should get a correct notion of the practical minutiæ of sanitary construction, so that for educational purposes the study of these diagrams should serve as the next best step to

Hosted by Google

the actual inspection of both good and bad existing systems. Every medical officer of health should possess a copy; he will find it very helpful. On the subject of cost (which is not treated in the "diagramettes") THE LANCET Commission on The Relative Efficiency and Cost of Plumbers' Work may, we venture to add, be consulted with advantage.

Cheese and Cheesemaking. By JAMES LONG and JOHN BENSON. London: Chapman and Hall, Limited. 1896. Price 3*s.* 6*d.*—Connoisseurs will read this little volume with considerable interest, and especially those chapters referring to the manufacture and character of continental fancy cheeses (Gorgonzola, Brie, Port du Salut, &c.). It contains chapters of not less interest also to the technical expert as well as to the scientific man. Thus the methods of manufacture are described as well as the principles involved. The popular, but apparently wrong, idea that Gorgonzola cheese is sometimes "greened" by means of copper wire finds explanation in the following: "When the texture of the cheese is found to be too close, so that blue mould will not grow freely, the cheese is pierced with metal skewers which admit the air, and with it oxygen, which the fungi require, for they are unable to grow in its absence." Mr. Long contributes an excellent chapter on the milk industry, and his remarks on what should be the quality of milk are, coming from one thoroughly acquainted with the technical side of the subject, well worth repeating. "There is practically no milk," he says, "the produce of a well-fed herd of cows, which contains at any time less than 3 per cent. of fat, but there are thousands of herds in which the average milk contains from 3·5 to 5 per cent." At present the analyst is bound to regard as genuine, milk containing 2·75 per cent. of fat, so that milk of good quality may be obtained by mixing rich milk with separated milk, and the product would come well up to the standard just referred to. Mr. Long gives good reasons for this standard being raised to 3·25 per cent. Of this section of the question he has had considerable experience, and as a result he finds that where a high standard has been enforced by law the consumption of milk, as well as its quality, has immensely increased, and he is satisfied that we should benefit the dairy industry of England in a high degree by instituting such a standard for ourselves. The same author contributes a chapter written on a similarly high level on the principles of butter-making. There can be no hesitation in bestowing praise upon a book which, like the one before us, is calculated to place certain home industries upon a more satisfactory basis and to elevate our standards of food.

The Medical Environment. By D. CAMPBELL BLACK, M.D. Glasg., F.R.S. Edin. Glasgow: Hugh Hopkins. 1896. Pp. 56.—The contents of this little book are two addresses delivered before a medical students' society, the subjects being respectively the Hospital Question and Medical Ethics or Etiquette. The author is well known as a controversialist who does not stand in awe of his opponents and is not slow to denounce unconvincing arguments. He seems, however, to be unnecessarily severe on hospital physicians and surgeons, who are described as "great purists in the matter of medical advertising. The secret of this virtue is that they do not require personally to advertise, as this is effectually done for them by reports and through the large *clientèle* which passes through their hands." On the other hand, the average feeling of the profession is distinctly in accordance with what he says in respect of the injustice done to general practitioners by the indiscriminate treatment of patients at hospitals.

Rough Notes on Remedies. By WILLIAM MURRAY, M.D. Durh., F.R.C.P. Lond. London: H. K. Lewis. 1897. Second edition. Pp. 104. Price 3*s.* 6*d.*—The favourable reception and consequent rapid sale of the first edition of this little book is the best possible testimony to its merits, so that it is, in fact, hardly necessary on the present occasion to do more than refer to the notice which appeared in our columns last July.[1] Arsenic, belladonna, mercury in various forms, and nitrate of silver are the drugs selected for illustration, the most remarkable of the cases quoted being an apparently hopeless one of dilated and hypertrophied heart in which a very protracted course of blue pill was undoubtedly the means of procuring ten or eleven years of comfortable and useful life.

JOURNALS AND REVIEWS.

Science Progress.—This publication is now a "quarterly," whereas previously it was issued monthly. Amongst the contents of the number before us is a remarkable paper with the paradoxical title Liquid Crystals, by Professor Miers, F.R.S., of Oxford. The title reminds us of the heading "Solid Solutions," which appeared in connexion with an interesting article in a previous issue. Yet both terms are justified by facts. As the author asks in this paper, How can a liquid be a crystal and how can a crystal be a liquid? However, under certain conditions drops of certain substances are found to behave just as crystals do, especially in regard to polarised light. They appear to be "doubly refractive drops which possess a symmetrical disposition of their peculiar optical properties, and are unlike any other drops or any other liquid previously described." The existence of these drops must lead to a new acceptation of the word "crystal," which will detract rather from the force of the word "crystallised," used so often and conveniently now as a figure in speech. "Condensation and Critical Phenomena" forms the interesting theme of another paper in the present number, while of particular interest is the paper on the Causes of Variation, in which the differences in form and structure which individuals of a species show among themselves are considered.

Cornhill Magazine.—Among the contents of the January number we can specially commend one advocating the setting apart of extensive tracts of land for the preservation of our indigenous wild animals and birds by Mr. C. J. Cornish, under the title, "The Making of a Paradise." These woodland or forest preserves, of which the New Forest in Hampshire is our best example, have already to some extent been provided by various landed proprietors—as in Wicklow by Lord Powerscourt, at Horsham, in Sussex, by Sir Edmund Loder, at Haggerston Castle, in Northumberland, by Mr. Christopher Leyland, &c. With quaint pedantry he calls a large preserve of this kind a "paradise," using the word as employed by Greek writers, such as Xenophon, who adopted it from the Persian. No reference is made to what was long ago done in this direction by Waterton, the naturalist. Under the heading of "Famous Trials" Mr. J. B. Atlay reviews the details of the Road mystery and the confession of Constance Kent, who committed the crime.

Westminster Review.—The most interesting article is one analysing the psychology of Anarchist conspiracies by Dr. Olindo Malagodi, who concludes that the danger from such agitations and conspiracies is much less than appear at first sight. "Predominance of the imaginative faculty, inaction, and mutual psychological excitation are the three fundamental elements of the colossal imaginings of anarchical conspirators." Successful plots have usually been carried out, not by Anarchists, but by Fenians or Nihilists, who have more definite aims. Mr. W. F. Bailey discusses the South-African question and predicts the establishment of a confederation more or less analogous to that existing in Canada. He also gives an account of the reasons which deter the Boers from granting full political privileges to the very mixed population of

[1] THE LANCET, July 4th, 1896, p. 31.

Hosted by Google

foreigners whom the goldfields have attracted to the South African Republic.

The Ludgate Magazine.—The opening pages are taken up with Chapter IX. of the Octave of Claudius. Fiction predominates in the present number, but there are many entertaining biographical details in Black-and-White Artists of To-day, and an article called Vignettes of the Invisible is illustrated by numerous photo-micrographs, chiefly entomological; nothing, however, can be said in favour of the one which professes to represent "a slice of a Londoner's lung, showing the smoke."

The January number of *Knowledge* has a well-written article from the pen of Mr. John Mills, F.R.A.S., on the Dawn of a Brilliant Era, being Part I. of the Science of the Queen's Reign. The article is embellished with the portraits of nine illustrious philosophers, including Edward Jenner and John Hunter, and there is a reproduction of a quaint engraving of George Stephenson's "Rocket," the forerunner of the modern locomotive engine.

The Quarterly Medical Journal for Yorkshire and adjoining Counties.—Mr. T. Pickering Pick (London) contributes a thoroughly practical paper on Intussusception in Children, recommending in the first place inflation with air, which may be effected by means of an ordinary enema pipe and a pair of common bellows; in the second place the introduction of fluid by irrigation or hydrostatic pressure, and immediate laparotomy if these fail. Dr. James Braithwaite (Leeds), who has performed symphysiotomy three times, discusses the operation from the general practitioner's point of view. The articles on Health Resorts are continued, Droitwich being selected this month.

The Contemporary Review.—Among other articles is a well-written paper entitled Bacteria and Butter, by Mr. G. Clarke Nuttall, giving an interesting summary of the results obtained by Dr. Weigmann of Kiel, who found that Pasteurised cream mixed with pure cultures of the acidifying bacteria yielded butter which was pure and could be kept for a long time, but was flavourless. He then prepared pure cultures of a milk bacterium which has the property of imparting flavour to butter, and by treating cream with a mixture of the two cultures a very superior quality of butter was obtained. It appears that such bacterial cultures are now on sale, both in the liquid form and as a dry powder.

The Journal of Pathology and Bacteriology.—In the second part of Vol. IV., published in December, J. B. Leathes and E. H. Starling contribute a paper on Some Experiments on the Production of Pleural Effusion, especially in connexion (1) with the effects of raised capillary pressure, (2) the effects of injury in the vessel walls, and (3) with the place of origin of the effused fluid, and they come to the conclusion that so long as the vessels are healthy no change in the pressure of the blood in the capillaries supplying the pleura is able to bring about pleural effusion; that in the exudation of pleurisy the chief factor is the increased permeability of the walls of the vessels in the subpleural and mediastinal tissues from which the fluid makes its way in the direction of least resistance—viz., into the pleura—and that in every case where effusion into the pleura is produced diminished absorption is associated with the increased exudation of fluid from the bloodvessels. E. A. Peters contributes a detailed but unconvincing paper upon Diphtheria and Pseudo-Diphtheria Bacilli, and Louis Cobbett and G. C. Phillips attacking the question from a somewhat different point of view are little more successful in throwing light on this subject. Sydney D. Rowland makes a contribution to the Study of Immunity in Guinea-pigs and P. Horton-Smith describes two new bacilli, one of which he names the Bacillus Proteus Urinæ, the other the Bacillus Excavans. Samuel G. Shattock has an interesting contribution on Calculi of Calcium Oxalate from a Cyst of the Pancreas, in which he discusses the modes of formation of these calculi and also their chemical composition. A Tumour of the Anterior Mediastinum arising from the Thymus Gland is described by H. D. Rolleston as partly a cystic adenoma of mucous glands and partly a hæmorrhagic chondro-sarcoma bearing considerable resemblance to certain tumours in the parotid region, but in this case the tumour arose from the thymus glands, although Hessall's concentric bodies were not present. T. N. Kelynack describes a Malignant Papilliferous Cyst-adenoma of the Kidney. An interesting and well-illustrated paper on Leukæmia with special reference to the Pathological Histology of the Blood and Marrow, is contributed by J. M. Buchanan. T. W. Eden continues his Study of the Human Placenta, Physiological and Pathological, in this part describing the ripe placenta, giving both the changes in the fœtal and maternal structures and arriving at the conclusion that the ripe placenta is a worn out and decadent or senile structure, the stages of development, maturity, and decay succeeding one another with great rapidity, and to some extent, overlapping. He goes on to say that the degeneration of vessels and atrophy plus degeneration of epithelial structures are changes associated with old age in all parts of the body, and that they are no more pathological phenomena than are the thickened arteries and wasted skin of aged persons. Joseph Griffiths contributes a paper on the Varieties of Ankylosis by Bone in different parts of the Skeleton; in this part of his paper dealing specially with the ankylosis found in different animals under different conditions, and also with the pathological, congenital, or pre-natal ankylosis. Altogether there is in this number a series of most interesting papers.

The *Veterinary Journal and Annals of Comparative Pathology* for December opens with an essay on Diseases of Animals Transmissible to Man, somewhat sketchy in character; a note on Rinderpest in South Africa, and a report of infection of Swine with Anthrax by W. R. Davis, F.R.C.V.S. A short account of a thirty-eight days' fast by a collie dog is given in which it is stated that at the end of a fortnight after the fast the animal was as fat as ever and is now alive and well. W. Williams, F.R.C.V.S., in his report on the Cattle Disease in Jamaica announces that he has come to the conclusion that the disease is a chronic form of Texan fever conveyed from place to place and transmitted from one animal to another through the intervention of the "tick." The infection is conveyed by the progeny of "ticks" which have matured on infected cattle and is inoculated by them directly into the blood of susceptible cattle. It is stated that two mild attacks or one severe one will probably prevent a subsequent fatal attack. In the appendix, or in a couple of appendices, T. A. Williams, M.B., reports on the Morbid Anatomy and Microscopic Appearance of the Wasting Disease. The blood presented the characters of profound anæmia, the number of red blood corpuscles being diminished often to one-seventh of their normal number; the hæmoglobin was also greatly diminished, though in less proportion; there was marked poikilo-cystosis, and in some of the cells there was a faint indication of nucleation. A number of banana-shaped or irregular rounded bodies which T. A. Williams does not classify are mentioned. W. Williams, however, thinks that they have nothing to do with the disease and that the "tick" is the real cause of the anæmia. The changes in the various organs are also described. Fluke disease (liver rot) and lung worms are dealt with in the second appendix. A number of clinical cases are recorded and the opening addresses at the various veterinary colleges and veterinary societies, with veterinary notes, abstracts, and reviews complete the number.

The Journal of Experimental Medicine, Vol. I., No. 4, opens with an article by James Homer Wright on the

Hosted by Google

Histological Lesions of Acute Glanders in Man and of Experimental Glanders in the Guinea-pig. He concludes that the glanders nodule in the cases studied by him is in no sense analogous to the miliary tubercle in its histogenesis, and he agrees with Tedeschi as opposed to Baumgarten that there is a primary necrosis of the tissue followed by inflammatory exudation, often of a suppurative character, degenerative changes rapidly ensuing in these inflammatory products. C. F. Martin and W. F. Hamilton describe Two Cases of Sarcomatosis with Purpura Hæmorrhagica in which the principal cause of the purpura seems to be an involvement of the vascular system by the sarcomatous elements. In a paper by John Lovett Morse the Changes produced in the Kidneys by the Toxins of the Staphylococcus Pyogenes Aureus are described and discussed. The observations made by this author go to prove that chronic interstitial processes are those which are specially met with in this condition. The Influence of Acute Alcohol Poisoning on Nerve Cells, by Colin C. Stewart, and the Action of Ether on Contracture and of Positive Kathodic Polarisation of Vertebrate Voluntary Muscle, by F. S. Locke, are both interesting and well-illustrated papers, as is also one by Winfield S. Hall and Marion D. Eubank on the Regeneration of the Blood. These latter observers come to the conclusion that the blood of apparently normal animals undergoes considerable variations within physiological limits; that the regeneration of blood after artificial loss is more rapid if there has been a transfusion of artificial serum, that this takes place less rapidly at first, gradually rising, and that once commenced the process carries the blood qualitatively considerably beyond the established normal; the quantity of hæmoglobin per volume of red blood corpuscles does not remain constant. G. W. Fitz contributes a Study of Types of Respiratory Movements from which he draws the following conclusions: (1) children of the two sexes differ very little in the character of their respiratory movements; (2) between girls and women and boys and men there is little or no difference in respiratory type; (3) child-bearing does not permanently affect respiration; (4) the natural type of respiration for both sexes is one in which the movement is fairly equally balanced between chest and abdomen, the abdominal type being somewhat in excess; (5) in typical unconstricted individuals the chest contributes about the same bulk of air as does the abdomen; and (6) constricting dress causes preponderance of thoracic movement in ratio to its restriction of abdominal movement and to the sensitiveness of the nervous co-ordination. F. G. Novy's paper on the Immunising Power of Nucleo-histon and of Histon is of considerable interest from the fact that Dr. Novy of all American workers has made this subject specially his own. He points out that although when injected separately nucleo-histon does not protect against the action of various toxins, when it is mixed with any one of them and then injected the toxin loses its specific action, but the animals injected are not rendered immune. Nucleo-histon acting on anthrax bacillus leaves it unaffected even after the lapse of eleven days. Histon has a somewhat similar action, whilst similar mixtures of closely related bodies, sero-globulin or albumoses, in Witte's peptone give analogous results. Histon, however, has marked toxic properties which are no doubt due to the hydrochloric acid present. This number completes a most interesting volume, and we congratulate American investigators on having such an excellent organ in which to publish the results of their work.

In the *Veterinarian* for December Mr. John A. W. Dollar, M.R.C.V.S., gives a long report on the Clinical Application of Jeyes' Creolin and Jeyes' Fluid in Veterinary Practice. Ringworm, pruritus, hen-lice, horse-lice, foul wounds, granulating sores, canker, thrush, and a number of similar conditions were all treated with these preparations with excellent results. At the same time it is pointed out that prolonged external treatment with creolin, especially when accompanied by friction, may give rise to somewhat serious results. A very good abstract of the annual report of the Board of Agriculture is given, and Mr. Finlay Dun's introductory address at the opening of the session of the Royal (Dick) Veterinary College is completed. An ambulance and operating table for dogs is figured by B. P. Godfray, M.R.C.V.S., and Mr. E. Wallis Hoare of Cork contributes remarks on Chloroform Anæsthesia. Clinical Cases and the Month's Progress and Reviews are exceedingly good.

Analytical Records FROM THE LANCET LABORATORY.

VALSOL PREPARATIONS (KLEVER).

(W. POPPELREUTER, 54, PORTLAND-STREET, MANCHESTER.)

THE Valsol oils are those which are known to the profession abroad as Klever's "Vaselina Oxygenata," and consist, it is stated, of pure hydrocarbon oils impregnated with oxygen. Their value appears to rest on the fact that they offer satisfactory vehicles for the administration of many medicaments. Thus "valsol" serves as a useful solvent for iodine, iodoform, ichthyol, creasote, creolin, eucalyptol, camphor, thiol, menthol, &c., and the clinical results obtained with the solutions of these agents in the oxygenated hydrocarbons are reported as very satisfactory. Creasote-valsol for example has been used, it is stated, with excellent results as an ointment in cases of pulmonary tuberculosis. The oil appears to be rapidly absorbed, carrying in with it the medicament. Ichthyol has been used in a similar manner in favus, and Iodoform-valsol and Creolin-valsol in gonorrhœa. The iodine preparation would appear to offer advantages, since it is stated that, despite the volatile character of the element, with the oil the iodine is also absorbed, so that a prompt action responding to the administration of iodine is obtained. Iodine-valsol has thus, it is claimed, proved to be a valuable local application in the treatment of syphilis. We have received various specimens of Valsol preparations containing in solution the medicinal agents already indicated. We found no difficulty in obtaining confirmatory evidence of the presence of the active agents stated on the label of each specimen. The preparations appear to be an introduction of importance in therapeutics, and no doubt will receive that trial at the hands of practitioners at home to which they seem entitled.

GLYCERINE PASTILLES OF PHENACETIN AND SULPHONAL.

(CURLING, WYMAN AND CO., 58 AND 59, BUNHILL-ROW, E.C.)

These pastilles consist of soft gelatin lozenges containing a definite dose of the medicaments indicated. They are offered as a convenient and palatable means of administering these drugs. The material is readily soluble and serves as an easy aid to swallowing the measured quantity of the medicament incorporated with it.

FRENCH LASILA.

(THE FRENCH LASILA COMPANY, 231, OXFORD-STREET, W.

Lasila is described as a mixture of "Toka" and chicory. "Toka" is a roasted seed about the size of a small nutmeg, which is offered as a substitute for coffee. The mixture yields a full-bodied, syrupy liquor with sweet taste, while it possesses certain aromatic characters derived from the highly roasting of the peculiar seed employed. It may serve to some extent as a substitute for coffee for those to whom coffee may be reasonably denied. Coffee, of course, like many other articles of food, leads, when immoderately indulged in, to gastric disturbances and other objectionable results; but

Hosted by Google

when used reasonably it affords an excellent beverage, serving, as is well known, as a decided stimulant to the nervous centres and augmenting the functional activity of the muscles. This effect is to be ascribed partly to the volatile oils which are developed in the roasting process and partly to the important proportion of caffeine it contains. "Lasila," on the other hand, contains no caffeine at all, although it possesses a strong aroma suggestive of the volatile oils of coffee. As might be expected, it yields a comparatively large amount of extractives soluble in hot water, but contains absolutely no alkaloid. It may be valued, perhaps, for its flavour, but for little else. It is probably harmless in moderate quantity, but it cannot be regarded as a true substitute for coffee, since it cannot possess those peculiar properties for which coffee is esteemed and chiefly consumed. From this point of view it is questionable whether it offers any advantage over pure chicory.

PRESERVED PEAS, BEANS, AND SPINACH.

(AGENCY: S. DUSSELSMA AND CO., 2, GRESHAM-BUILDINGS, BASINGHALL-STREET, E.C.)

We have carefully tested these preparations with the view of ascertaining whether any exception can be taken to the method adopted for the purpose of preserving. Not only did we find on experiment that the vegetables were free from copper salts, which are so frequently employed as a greening agent, but also that they contained no objectionable preservative or any form of metallic contamination. No objection, therefore, can be reasonably urged against the employment of these articles as really wholesome food. The original flavour of the vegetable appears to have depreciated but little, while the appearance is not unsatisfactory. In these preparations we find an instance of certain articles of food being satisfactorily preserved for general consumption without the aid of chemical substances. We are, therefore, justified in speaking of them in terms of praise.

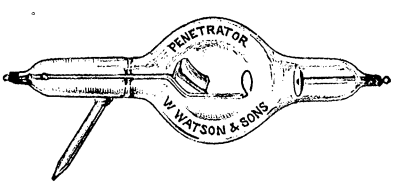
BAYER'S SPECIAL DRUGS.

(AGENCY: THE ELBERFELD FARBENFABRIKEN CO., LIMITED, 19, ST. DUNSTAN'S-HILL, E.C.).

Although English chemists were chiefly concerned in the discovery of the building up of organic compounds, yet Germany now takes the lead in the manufacture of the great number of synthetic remedies which are at the disposal of the medical practitioner. Foremost amongst those who have made practical application of synthetical chemistry are the above well-known firm, whose laboratories are at Elberfeld. We have recently received specimens of various drugs to the purity of which special attention is given. Amongst these are the following: Lycetol, the tartrate of dimethyl-piperazine, which is employed to increase the alkalinity of the blood, and, therefore, as a uric acid solvent; Salophen, a yellowish-white crystalline powder, said to be preferable to sodium salicylate or salol in the treatment of rheumatism as an anti-rheumatic and analgesic; Phenacetin, a well-known anti-pyretic and anti-neuralgic, which may with advantage be combined with salophen in influenza; Trional, a hypnotic, said to be without effect on the circulatory, respiratory, or digestive apparatus, while its action on the temperature and secretions is without objectionable effect; Europhen, an iodoform substitute, spoken well of in dermatological and gynæcological practice; Tannigen, a combination of acetic acid and tannin, passing the stomach unchanged, but exerting an astringent action in the intestinal tract; Losophan, an odourless white crystalline compound of iodine and cresol, of high antiseptic power, chiefly serviceable in parasitic and skin diseases; Iodothyrin, the now well-known active principle of the thyroid gland, combined with sugar and milk, in such quantity that one part of iodothyrin is equivalent to one part of the fresh gland; Somatose, a powerful nutritive consisting largely of albumose; Analgen, similar in composition to phenacetin and employed as a powerful antipyretic in neuralgia and acute rheumatism; Aristol, a useful application for burns, parasitic eczema, and ozæna; Sycose, an artificial sugar in several forms, one said to be 300 times sweeter than sugar, another which is much more soluble, 475 times sweeter than sugar, and another which is pure sycose and not a soluble sodium salt, 550 times sweeter than sugar. All these drugs give evidence of careful preparation.

COMPOUND PHENACETIN TABLOIDS.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL-BUILDINGS, E.C.)



The object of this combination is obvious to our readers. Phenacetin, as clinical testimony has shown, is a useful analgesic and antipyretic, the action of which it may be desirable to modify by means of a cardiac stimulant such as caffeine. The combination is said to be particularly useful in relieving the sick headache of migraine.

New Inventions.

IMPROVEMENTS IN X RAY APPARATUS.

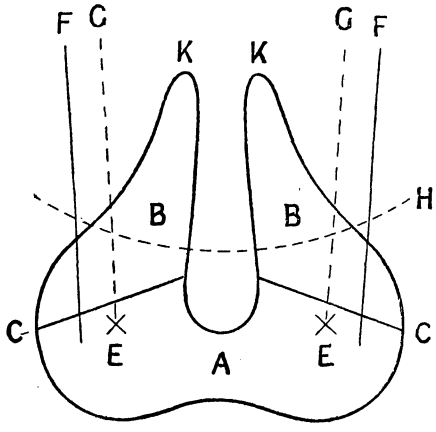
As the conditions under which the x rays are produced are more understood so improvements are effected in the structural details of apparatus required from time to time. The discovery has led to an enormous demand upon the resources of vacuum tube makers, and the makers also of induction coils, while secondary batteries can hardly be made fast enough to keep pace with the increasing requirements, and barium platino-cyanide, once a compara tively rare compound, is now sold in the form of a paint upon a screen in tolerably large quantities. Improvements in one or another of the directions just indicated have been brought to our notice by the following firms.

Messrs. W. WATSON and SONS of 313, High Holborn, W.C., have recently introduced what they call the new "penetrator" focus tube, the construction of which will be seen from the accompanying illustration. Whatever views may be put forward as to the action of

this tube, it certainly gives brilliant results, and that with a minimum of current passing through it. To begin with, one important advantage it offers is the fact that the electrodes to which the wires from the induction coil are attached are as wide apart as possible, so that discharge between them and outside the tube is practically impossible. Then the anode from which the x rays proceed is made quite rigid by means of a small beam of glass across the narrow part of the tube. This is important, since if the deflecting disc or anode vibrates, as is the case with some tubes, good definition either in a photograph or in the shadow on the screen can hardly be expected. The deflector is parabolic in shape and in front of it in the same plane is a loop of wire which is said to serve two purposes—namely, that of directing the rays straight on to the deflector and of absorbing traces of gas in the space, giving them out again on gentle heating, so that the degree of vacuum is easily regulated by this means. We have not tried this tube for producing photographs, but with the screen it gives most

Hosted by Google

satisfactory results; the detail is good and the shadows sharp. It is specially well adapted for viewing the deep structures of the body. Moreover, it works well with a current equal to the discharge of a two-inch spark in air, or even less. Lastly, a very important but simple improvement in the tube consists in the fact that the terminals are very strong and not likely to be broken during the constant disconnexion and connexion of the wires.



The GENERAL ELECTRIC COMPANY of 71, Queen Victoria-street, are devoting special attention to the requirements of a satisfactory x ray equipment. They have introduced for the purpose a powerful coil of "best Manchester make," in which the important feature consists of a fine adjustment attached to the contact breaker, so that a steady contact is maintained and a uniform discharge in the focus tube. The company provide also focus tubes, fluorescent screens, and secondary batteries.

Messrs. HURST and Co. of 53, Leadenhall-street, are also providing some excellent apparatus which intending purchasers have the advantage of testing at the laboratory of this firm before completing their purchase. They supply best English-made coils and both English and continental patterns of focus tubes. They are introducing an excellent fluorescent screen, the barium platino-cyanide being rendered absolutely homogeneous and uniform by means of amyl acetate. As might be expected, the shadows are remarkably sharp and well defined, making the screen of particular service for viewing the deep structures of the body.

A DOUBLE-PEAKED CYCLE SADDLE.

MR. W. STEPHENSON RICHMOND, M.R.C.S. Eng., writes: "This saddle consists essentially of a fixed back part, A, to receive the main weight of the body, and two moveable flaps, B B, for the support of the upper part of the thighs, and forming at the anterior points the moveable peaks, K K. These flaps are supported beneath by a balance (Fig. 2, D). When one prolongation is pressed down the other one is

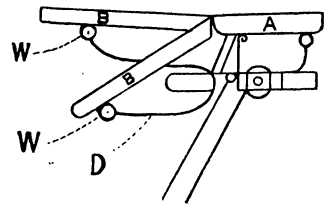


FIG. 1.

A, Back fixed part. B B, Flaps. C C, Hinged joint. E E, Position of tuberosities. F F, Lines of femora. G G, Lines of flexor muscles. H, Line of grip.

forced up, so that in riding they follow automatically the up-and-down movements of the thighs. The entire surface is padded with horse-hair and covered with leather. There are no depressions for the tuberosities of the ischia, but their position on the seat is indicated by the crosses at E E (Fig. 1). There is no central peak, and absolutely no perineal or sub-pubic pressure. The line, H (Fig. 1), shows the grip which is obtained of the flaps, which, by extending to K K, supply the ly useful function of a peak. The advantages claimed for this saddle are—(1) no central pressure; (2) increased sitting surface; (3) support and alternate rest of the muscles of the thighs; (4) alternate relief of pressure on the tuberosities; (5) no friction of the inner surfaces of the thighs; and (6) at the same time all the advantages of a peak with a comfortable seat and absolute protection from injury to the delicate soft parts beneath the pubic arch. The relief from the continual grinding on the tuber ischii so often complained of by cyclists is obtained by part of the weight of

FIG. 2.

D, Balance. W, Small wheels or ball socket endings.

the body being alternately thrown on to the prolongations at the downward thrust, and by the contraction of the semi-membranosus, semi-tendinosus, and biceps in the line G (Fig. 1). Instead of a hinge at C (Fig. 1) and a balance at D (Fig. 2), the saddle may be made of one piece of tempered steel resting on adjustable springs beneath. The saddle is made by Mr. Lycett of Birmingham. A model may be seen at Mr. Alfred Cox's, surgical instrument maker, 108, New Bond-street, S.W."

Of course it remains to be seen how this saddle will work in practice, but theoretically and from an anatomical point of view it would appear to be constructed upon a sound basis.

"HORONIT."

MR. JOSEPH T. SZCK (Hotel de Provence, Leicester-square, W.C.) has submitted to us a specimen of this substance which is made from hoofs and horns and which is said to form an excellent material for stuffing mattresses, cushions, beds and other articles. It consists of white, light, soft, elastic flakes obtained from horn shavings, and its cost of production is, it is stated, less than 1½*d.* per pound. It is certainly well adapted for the purpose so far as its non-conductivity is concerned. One drawback to its use, it might be supposed, would be the fact of its generating an unpleasant smell when slightly warmed, but one important claim in its favour as a stuffing material is, that this tendency to smell disagreeably is completely removed by first treating it with a weak solution of peroxide of hydrogen. Testing the crude material, for instance, by simply warming it or treating it with warm water or even with alkali, a very disagreeable smell, we found, was evolved, which, despite any other satisfactory property, would quite preclude its employment for the purposes already indicated. On soaking, however, the substance in a weak solution of peroxide of hydrogen for twelve hours in the dark the material became quite free from smell even under the most aggravated trial. This is the essence of the patent. The treated material is very well adapted for mattresses and, in fact, in all cases where a non-conducting and at the same time yielding material is requisite. In addition it is absorbent, so that it is proposed to employ it in hygienic bandages. Further, if at any time it should become unsuitable for use the material can be replaced, and the old material, containing a very high percentage of nitrogen, is said to be valuable for agricultural purposes. While we doubt whether this would ever become a practicable expedient or constitute a point in favour of its adoption, yet there is reason for believing that "Horonit" may prove useful for the purposes for which it is designed.

THE LANCET.

LONDON: SATURDAY, JANUARY 16, 1897.

THOSE who study the overcrowding of the profession and who see in it the chief cause of certain methods of practice which we all lament will not find much comfort in reflecting on the statistics of the profession which we published last week from the Medical Directory. According to this excellent authority the profession includes 958 names more than the year before, a larger increase than has ever before occurred in any previous year, except 1894. The increase is ubiquitous—in England, Scotland, and Ireland, in registered practitioners resident abroad, and in medical officers of the naval, military, and Indian services. It is not likely that there is any serious error in the figures. But before finally concluding that the increase is exactly so great as is here represented we shall do well to wait for the Medical Register. Neither record is infallible. There are numerous defects in the channels of information. One fact alone is significant. In the Assistant Registrar's Report to the Branch Council for England as to the voting in the recent election for Direct Representatives he showed that of the voting papers sent out no less than 1137 were returned through the Dead Letter Office. Of course this in no way represents the mortality of the profession. But it shows how difficult it is to arrive at very accurate results owing to the shifting and migratory condition of a large section of the profession. There is another fact to be taken into consideration in considering these large additions to the profession. They still continue to represent to a certain extent the numbers entering under a four years' curriculum, and may not be sustained when the full effect of the lengthened curriculum comes into operation, as it will shortly do. Still it is obvious that there is a rush into the profession far beyond what is necessary to supply the public with medical assistance or the members of the profession with such employment as will recoup them for years of laborious study. It is noticeable that London has twice as many practitioners (1 in 850) as the provinces. But the place which is blessed with the largest proportion of medical men to population is the Scotch metropolis. Edinburgh has 1 practitioner to 500 people Dublin comes next with 1 to 600. It would seem as if in these places the activity of medical education and the number of medical schools in proportion to the population had an effect of drawing or detaining practitioners, many of them depending as largely on teaching as on practice.

It is interesting, and it is very important, to discover what are the causes of this undue increase in the number of medical men. We say undue, because the increase is out of all proportion to the increase in population and to the needs of the public. Mr. GLADSTONE in his address to a meeting for the promotion of a memorial to Sir ANDREW CLARK magnified the position and the prospects of the profession—it was "a position continually advancing and continually rising." "The position is becoming one," he said, "of vital and commanding importance." Many see in the progress of civilisation and the increase of knowledge the removal of gross causes of disease—bad air, insanitary dwellings, intemperance, vice and crime, unhealthy employments, and long hours of labour. But, according to Mr. GLADSTONE, with the increase of health and invention and discovery will come an increase in "wants" and "enjoyments," and in connexion with this increase in wants "there will be an increase of infirmity and disease," and so an increased demand for the profession that is expected to postpone infirmity and to cure disease. It is a singular tribute to medicine, insensibly paid to it by thoughtful persons, that it has such powers and that it can both postpone infirmity and remove disease. And so it has. But its authority will have to be much more extensively recognised than it is and society will have to place the medical profession on a much higher pedestal that it has yet given it before its powers for good, its full power over "infirmity and disease," can be exercised.

We cannot stay to discuss more fully the reasons why we do not see in Mr. GLADSTONE'S theory the explanation of the growing numbers of the profession. His view is profoundly true. But it is an explanation of the growing importance of the medical art rather than of the growing numbers on the Medical Register. We have still to explain these, and the explanation is not easy. The cases of Edinburgh and Dublin would tend to show that medicine is followed by many as a teaching profession as well as a practising one, and undoubtedly the enormous development of medical education and medical examination makes many registered practitioners comparatively independent of medical practice. Then, again, the progress of general education increases the disposition of young men towards professionalism of some sort. This has been the effect of sound general education in Scotland for generations, so that, although a comparatively poor country, it has supplied the learned professions with a large proportion of members in England and the colonies and the empire generally. A better system of general education, extending through every class, is having a similar effect in England. The Bar attracts many who never expect to live by briefs. Can it be that men are entering the medical profession for its mere status, not expecting practice? We do not so read the signs of the profession. It does not attract, as a rule, wealthy men who can afford to live without much income from practice, as the church and the law have largely done. There are, of course, teachers of medicine and men of research in the profession living on incomes which many general practitioners would despise. As a rule, men entering the profession expect to live by it and to be efficient practitioners. They should be able to live without anxiety, which is not the lot of a large number of those now crowding into its ranks. One circumstance tends to convey to the public an exaggerated idea of the profitableness of the medical calling—that is the faith and frequency with which they see medical men putting their sons into it. It is to no purpose to protest that the medical profession is going to

Hosted by Google

ruin while medical men can be found everywhere putting two, three, four, or six sons into it. This is scarcely consistent. We only in these observations touch the fringe of a great subject. We have a high hope of the future of medicine, but this future is not to be realised by mere numbers. Excessive numbers will rather mar than make it and will tend to depress the prosperity and reputation of medical work.

IT is not infrequently desirable, in deference to the claims of expediency, to modify the application of recognised principles. Sometimes, indeed, in a particular scheme it is found that more or less sacrifice of what is in itself excellent has to be made in order to obtain the best available results. With regard to the enlargement or re-building of its Royal Infirmary the city of Manchester appears to find itself in a position of this sort at the present time. Other things being equal, the pavilion system of hospital construction or some analogous system, such as that of circular wards, has well-recognised advantages. It allows all possible benefit to be got out of natural ventilation, and exposes the wards—especially where the buildings are of only one storey or are well separated from each other—freely to the health-giving influences of sunlight and it tends to prevent over-crowding on site. In a large city, however, building-ground is limited in amount and is very costly, while hospital pavilions require much space. An institution intended to serve a whole community may not conveniently be removed too far from a central position, especially if the city itself occupies a wide area relatively to its population, and it would almost seem as if this must be the case in Manchester, with the great majority of the people living in houses on the ground level and not in tenements of flats superimposed on each other. It is alleged—whether following the old adage, "out of sight, out of mind," we know not—that if the Royal Infirmary were removed from its present commanding position subscriptions would largely diminish, and this is a consideration of the first importance where maintenance depends on the goodwill of the public. In the case of a fever hospital, which is chargeable on the rates, the matter is different.

The question of architectural appearance is also receiving notice by those who are discussing the subject in Manchester. It is easy to make too much of this. Even a millionaire does not design his dwelling-house to resemble a cathedral, though a cathedral might be more pleasing to the eye than a mansion. Appearance must always be subordinate to use. Obviously, however, the site occupied by the Manchester Royal Infirmary ought to be the *locus* of a very handsome edifice of some sort, and if the Infirmary is to remain there it must be made an ornament to the city. It is urged by Dr. HARDIE, who advocates the present site, that the pavilion system of construction which, despite the fact that St. Thomas's Hospital is not an architectural failure, does not readily lend itself to building schemes of striking effect, is not now essential for the welfare of patients. He holds that artificial ventilation and antiseptic surgery have altered the conditions of success since the times of FLORENCE NIGHTINGALE and Sir JAMES SIMPSON. With regard to artificial ventilation it cannot be denied that there is much force in his contention. A great deal depends on details of arrangement, but in many places artificial ventilation has been, and is, a success. In populous places artificial ventilation has this distinct advantage, that it alters the standard of purity of the air-supply. With natural ventilation the standard must be the immediately surrounding atmosphere in its existing condition. With artificial ventilation the air can be washed and cleansed before its admission into a building. In smoky Manchester this must be of special consequence. Further, the possibility of safely and pleasantly changing the air of an apartment every six minutes instead of every twenty minutes must be taken into consideration with regard to the air-space required for every patient in a hospital, for within reasonable limits cubic space may be diminished accordingly as air-supply is increased. We say within reasonable limits, and this reservation is necessary if we are to profit by the lessons derivable from the experiences in the hospitals of the Metropolitan Asylums Board regarding the influences of aggregation on the prevalence of post-scarlatinal diphtheria and the spread of small-pox from hospitals, though at the Manchester Royal Infirmary these diseases, needless to say, are not admitted.
